No. 1.

# Notes and Comments.

At a City inquest last week, the Experiments Coroner very properly drew attention to a fact which we think should be understood in all its bearings. Patients. The institution at Battersea which rejoices in the title of the "Anti-Vivisection Hospital," was called upon to treat a little girl who had an injury to the head. The wound was examined by the resident medical officer, a gentleman who has been qualified for close on thirty years, and stitched up by a nurse. Somehow or other the child appears not to have attended frequently, and some weeks later she was admitted to St. Bartholomew's Hospital with cerebral abscess, a condition which, in spite of operation, eventually proved fatal. We do not wish to deal with this aspect of the question, but to the one which struck the Coroner, namely, that on the annual report of the Anti-Vivisection Hospital appeared the words, "No Experiments on Patients." The secretary, when questioned as to the meaning of this phrase, said that the poor were often shy of hospitals, and denied that it suggested that experiments were performed on patients at other hospitals. The solicitor who appeared for the hospital admitted that he had heard it said that surgeons liked to try experiments on poor patients in hospital, and the matter seems to have stopped at that.

on the Public.

WE think the Anti-Vivisection Hospital is very lucky to have got out of the quandary so easily. The title "Anti-Vivisection Hospital" either means that other hospitals are pro-

vivisection, or nothing. As a matter of fact, of course, no hospital qua hospital is vivisectionist or anti-vivisectionist, although in the schools attached to a few teaching hospitals experimental physiology and pathology is taught. If, however, any doubt existed as to the real meaning of the title, the printing of the words "No Experiments on Patients" would show what is intended. It is only en pièce with anti-vivisection methods that such a scandalous innuendo should be thrown out against the great charities of England. There can be no doubt in the mind of any impartial person what is intended by printing these words in the report, and we have no hesitation in saying that they stamp the institution as a disingenuous one in spirit and method. The experiment that is being made by it is an experiment on the credulity of the British public, and it is employing the most cruel and heartless manner of making it. The old lies put about by anti-vivisectionists about experiments on hospital patients have been exposed again and again, but the anti-vivisectionist hospital does not hesitiate to trade on the superstitions of the poor of Battersea.

Ad Nauseam. MR. COLERIDGE, who, to do him justice, has frequently repudiated the Batersea institution, has lately given another example of the same persistency in anti-vivisectionists

dishing up the same old story, which is shown to be untrue each time it appears in print. In the Times, last week, Sir Victor Horsley again took him to task for propounding the worn-out fable about Dr. Crile's experiments on shock. It may be remembered that, in order to determine certain points, at certain stages of some of the experiments the animals were allowed to come so far out of surgical anæsthesia as to show reflexes, though, of course, absolutely unconscious of pain. The terms "incomplete anæsthesia" and "light anæsthesia" were used to describe this condition, and Mr. Coleridge, seizing on these words, and knowing nothing about anæsthesia, has attempted to make capital out of them for nearly ten years. We hoped that his avaragement before the Basel Committee that his experience before the Royal Commission on Vivisection would have had the effect of sobering him and making him adhere more closely to fact, but even the pitiful figure he cut there seems to have left his faculty for distortion but little impaired.

Ambulance Training.

BEFORE leaving the subject of "experiments" on patients, it is well to notice the type of feeling on the subject which prevails even in certain educated people. The

Paddington Board of Guardians, a little while ago, passed a resolution allowing twenty men of the 1st City of London Field Ambulance R.A.M.C. to attend their infirmary to receive instruction in the application of splints and in the dressing of wounds, on the understanding that no patient was to be dressed by them without previously giving his consent. One guardian, Colonel Maunsell, strongly objected to the arrangement, declaring that patients should not be practised on, even with their consent, and another gentleman supporting him, the question is to be re-opened shortly with a view to rescinding the resolution. Now, it is hardly necessary to say that every proper step that can be taken to protect hospital patients—pauper or eleemosynary -should be taken, but it is equally obvious that unless would-be beginners practice on some such person they will never be beginners at all; and one generation will suffice to see the extinction of doctors and all attendants on the sick. Students and ambulance men must learn on someone, only they must do so under strict tutelage and supervision. Even at the Anti-Vivisection Hospital it would appear that nurses are allowed, under the medical officer, to sew up wounds, though that is the only institution we know of in London where

such a practice is permitted. So that if the Paddington Guardians do as they are asked, and go back on their resolution, they are likely to throw the wounded Territorial soldier of to-morrow into the hands of men who have never been taught to handle or deal with a sick man.

"Rotten,
Ripping, and
Right-oh!"

The benevolent and public-spirited gentlemen who sit on the Walsall Education Committee seem to take their duties so seriously that anything in the nature of pleasantry is

regarded as an offence against the decorum that should characterise that dignified body. The actual facts of the case are difficult to ascertain with accuracy, but Dr. Stead, Vice-Chairman of the Education Committee, seems to have pained his serious-minded colleagues by what one of them described as a "disgraceful attack on education." Mr. Leckie, the gentleman in question, was almost paralysed when he read it. "The doctor," he asserted, "had said he had no sympathy with algebra." It may be an unfortunate result of medical training, but we confess to having very little ourselves; but let us hasten to add, we hold the study in great veneration, perhaps all the more because of our own ineptitude for it. Still, we admit that a gentleman who can publicly proclain his distaste for algebra is just the sort of person who might be led into making disrespectful remarks on the equator. But had Dr. Stead stopped there he might have escaped the worst. Unfortunately, he angered his colleagues more by referring to the three R's as "Rotten, Ripping, and Right-oh," "a quotation," said his critic, "from a low-class journal." Dr. Stead, when he rose to reply, was unabashed, admitted his crimes, and said it was the first time he had heard Punch called a low-class journal. Verily, as Mr. Dooley has told us, a hard life is science.

The Rich
Kleptomaniac.

A RECENT police court decision by a metropolitan magistrate raises points that appear to deserve comment from the social as well as the medical point of view. Shortly before

cal point of view. Shortly before Christmas Day a lady visited certain stores, where she was detected in the act of carrying away a quantity of articles that had been stolen. culprit was defended in court by learned counsel. who stated that she was in affluent circumstances and occupied a good social position. It seems almost incredible that she was permitted to remain nameless throughout the trial by an Englishman occupying so responsible a judicial position as that of a London stipendiary. Yet that is what occurred, the defendant having been dismissed on payment of three guineas costs and on her medical man's recognisance of £20 for her appearance if called upon for judgment within twelve months. This leniency was apparently on the ground of mental irresponsibility for her actions, and she was allowed to leave the court without having disclosed her name and address from first to last to the police. This novel departure in the administration of a summary court may safely be left to the consideration of Parliament when it reassembles. In the case, say, of Jane Smith, of Leather Lane, she is liable to have her name and address published in full, not to mention her age, when brought before the magistrate for any offence whatever, no matter how venial or trivial. Why another female, having committed a felony, is to be allowed to conceal her name and address, simply because she happens to be wealthy and to live in Belgravia, is one of those mysteries of the law that at times spring up to perplex the popular mind. As a matter of fact, Mr. Francis, the magistrate in the above case, had two other charges of stealing from the same stores brought before him. One, a housekeeper, was sentenced to two months' imprisonment without option of a fine, and the second, a nurse, was remanded.

Why not a incident requires just as much unravelling. If a Belgravian lady Kleptomaniac? steals a number of articles suitable

for presents shortly before Christmas, there is a clear motive for the departure from the ethics of her class. If Jane Smith, of the address aforesaid; purloins a goose to provide a New Year's dinner to her starving husband and children, her motive is equally apparent, and from the humanitarian point of view less culpable. Yet the Belgravian lady has been allowed to go away without punishment and without disclosing her identity. The magistrate apparently accepted her counsel's plea of irresponsibility-in other words, that she was a kleptomaniac. As scientific men, we recognise the possibility, and even the probability, of that assumption, but, as logical men, we cannot restrict the plea of mental irresponsibility of that kind to one class of society. If there are rich kleptomaniacs, there must be also poor kleptomaniacs. In reports of police cases it often happens that the motive of an offence is absent or ludi-crously inadequate, but the plea of irresponsible theft on the part of a poor person would be laughed out of court incontinently, while the desire to remain anonymous would be regarded as an aggravation of the original offence in every step of the legal processes to which he would be sub-The plain truth appears to be that criminal iected. law administration has not yet been illumined by the faintest glimmering of the workings of the insane mind. Scientific medicine is perhaps partly to blame, for the minor criminal has been hitherto neglected by alienists, very much as he has been ignored by society. Now and then a wealthy offender who can command counsel is able to deflect the artillery of the police courts. But why should there not be standing experts in all our police courts to protect the unfortunate representatives of what may be described as minor criminal insanity? To complicate the affair still more, the magistrate concerned has since declared the name of the well-to-do kleptomaniac was known to him all the time, although the knowledge does not appear to have been conveyed to the police!

# LEADING ARTICLES.

THE METROPOLITAN HOSPITAL FUNDS AND THE SMALL HOSPITALS.

Were the fate of the small hospitals of London to be dependent on the good-will of the King Edward and the Hospital Sunday Funds, there is little doubt that they would speedily cease to exist. The non-representative constitution of those two bodies prevents any adequate defence of the interests of the lesser institutions. The Hospital Sunday Fund has now abandoned its independency of action in this matter, and has endorsed the policy of the King Edward Fund in witholding grants from all but flourishing and large medical charities. On the other hand the Hospital Saturday Fund continues to support the small institutions with liberal and increasing allocations of money. The key to the

attitude in the last-mentioned case is probably not remotely concerned with the fact that the Saturday Fund is a representative body governed by men drawn from the hospital patient class and from representatives of the smaller medical charities. The Saturday Fund, however, does not limit the qualifications for its franchise to purely democratic lines, for the large institutions are represented as well as the small, and among its principal officers are included men of social prominence who are, as a matter of fact, commonly drawn from the governing bodies of the two other Funds. It is clear, then, that the constitution of the Hospital Saturday Fund is representative of all classes concerned in its administration; in other words, it is under popular or democratic representative control, as distinct from the pure irresponsible autocracy that governs the King Edward Fund. Under these circumstances, it can hardly be without significance that the democratic body, which knows the medical charities from within their walls, supports the small hospitals, which are, with few exceptions, ignored by the Metropolitan Sunday and the King Edward VII. Funds. It may reasonably be asked why the latter bodies should hesitate to have representatives of the small hospitals on their governing bodies. Before the creation of these distributing agencies the small hospitals were supported by the public, whose contributions have been to a very large extent diverted to the Funds, with the result of great and, in some instances, of disastrous loss of income to the smaller institutions. Surely the Funds have a moral responsibility towards the organised charities which they have thus unintentionally damaged. At any rate, we maintain that if in the course of their administrative duties they find that certain institutions, be they great or small, are unworthy of support, then they should say so publicly and give their reasons, so that the public and the institutions thus singled out may know what is complained of, and be afforded an opportunity of putting their house in order. Without representative control and without the right of appeal, the King Edward or any other public administrative body must always be liable to obvious abuses. The principles of the Star Chamber have always been repugnant to the Anglo-Saxon, yet it is difficult to see how they differ materially from that of a Fund which lacks popular representation and control, and which is able to withold public trust money given for a specific purpose from certain institutions entitled to share in that benefaction, without stating the reasons for such a serious and damaging step, without defining its lines of action, and without affording any chance of appeal against its absolutely autocratic actions. Can it be wondered at if in certain quarters the cry is raised at some future time that this or that Fund has been captured in the interests of a class? In France it is said that the Pasteur Institute has attained wealth and influence so great that it practically controls the majority of hospital appointments. Something of the same kind appears to be taking place in London in the case of the two younger Hospital Funds. The recent experience of the Hampstead Hospital appears to show that the Funds are attempting to exercise an undue influence in the matter of hospital appointments. Amalgamation was first of all thrust upon the Hampstead

Hospital in a way that could hardly be evaded. and then the appointments in the consolidated institution were handed over to the consultant class of medical men, who practically alone are represented in the King Edward Fund. There is, of course. nothing to be said against the private character or the professional skill of the gentlemen who accepted those appointments, but the fact remains, or, at any rate, appears to remain, that they are, to all intents and purposes, nominees of the Funds. If that be not the case, we invite a correction, and shall be only too happy to learn from an authoritative source any alternative explanation that may be forthcoming. That the affair is evidently not acceptable to the medical profession as a whole may be inferred from a "warning notice" in the British Medical Journal, which has been regularly inserted ever since the resignation of the general practitioners who originally staffed the Hampstead Hospital. If the Funds attempt in the future to exercise their influence in the matter of hospital appointments they will probably come into collision with the rank and file of the medical profession. Nor is it easy to gather why any such attempt should be made, except, possibly, on the ground that certain interests have gained an undue amount of influence upon autocratic governing boards. The work of the Metropolitan Funds is noble and enduring. It is extensive enough in its legitimate and proper function of the administration of public trust money to engage the whole energies of the philanthropic gentlemen who give their services so freely and unremittingly to its advancement, Above all, our thanks are due to His Majesty the King for having originated so great and useful an undertaking, and to the Prince of Wales for the active personal interest he has shown in its work. At the same time we have felt it our duty to point out what we consider to be defects in the present system, and we give free utterance to these criticisms, in the sure confidence that they will be received in the highest quarters with that breadth of wisdom and of liberal sympathy that has always characterised the relatives of the present dynasty with all classes of its loval and devoted subjects.

# CURRENT TOPICS.

# The Hospital Note System.

At the present time it may be doubted whether any large section of the philanthropic community would be found to favour the system of hospital notes. The best that can be said for that method is that it furnishes an excellent and, sometimes, a much-needed stimulus to charity. It must be a somewhat weak-kneed generosity, however, that needs that sort of patronage by way of recompense, On the other hand, the trouble and inconvenience inflicted upon the poor must be simply incalculable. Take the case of a patient suffering from incipient phthisis, who has applied for admission to a special hospital for the treatment of consumption. No matter whether his case be curable or hopeless. ninety-nine times out of a hundred he has to procure an in-patient letter before his name can be placed on the list. To procure the letter he has to make a round of visits to subscribers, and he may even eventually give up the task as hopeless, especially in view of his state of health. From a

general point of view, it is clear that the more seriously ill the applicant, the less fitted he is to undergo the fatigue and loss of time involved in the search for an in-patient letter. Now that hospital funds have become the intermediaries between the benefactor and the beneficiary, the stimulus of the hospital letter will be less and less applicable-unless, indeed, hospital funds should at any time be forced to augment their incomes in that undesirable way. It would be perfectly logical for the funds to grant letters to subscribers in proportion to the amount of their subscription. It is to be hoped, however, that the day is not far distant when hospital letters will be relegated to the limbo of obsolete machinery, and when the bare facts of being poor and of being sick will be enough to secure instant admission of the worthy to a well-equipped hospital. Were a proper exclusion of well-to-do patients made, there is some reason to believe that our existing voluntary hospital accommodation would be rendered more adequate to the needs of the sick poor.

# Ventilation of Railway Carriages.

It is not surprising that, at this time of year, when the weather is so changeable and travelso frequent, there should be much grumbling about the ventilation and-what is the counterpart of ventilation—the warming of railway carriages. The trouble is specially experienced on the south and short-journey lines, though the longdistant trains are by no means perfect. It is monstrous that, in the year 1909, passengers travelling for two or three hours into the country should have no means of warming a railway carriage except a foot-warmer, and that even that humble attempt at comfort is only to be obtained at a terminus, or through the good offices of an obliging and well-tipped porter. In an Arctic railway carriage we can hardly blame the most air-hungry for shutting all windows as tightly as may be, and warming themselves with the moisture exhaled by their fellow-passengers. In a railway carriage containing, say, eight people, it is highly probable that at least one has, or has recently recovered from, a cold, if nothing worse, and it is still more highly probable that in the bacterial forcing-ground in which he has sat he will have infected two, three, or four of his fellow-passengers. The ventilation of railway carriages in winter depends primarily on adequate heating arrangements, and we cannot think how the public, year after year, allow the railway companies to flout their health and comfort with supercilious disdain.

### Hygienic Corks and Sanitary Bottles.

AMONG the few avenues of death yet unexplored by the enterprising bacteriologist, we learn that the humble cork, which for so many hundred years has stopped the refreshment bottles, is no longer to escape attention. A French medical man, Dr. Bourdas, has sounded the toosin, and war to the knife—or, perhaps, we should say, to the corkscrew—is to be waged. The seemingly harmless cork, it seems, is a rogue of the worst character, because, long before entering its long resting-place in the mouth of the Lottle—indeed, while still attached to its native bark—bacteria have found and fed

upon it. What these bacteria are and what effect they have on human or cork life are not very clear, but nowadays bacteria-by a certain school-must be shot at sight. If it is bad to use new corks, how much worse to use old ones? Dr. Bourdas seems to wonder how anyone can survive the ordeal. When we come to think of it, we are not sure we have not unconsciously lighted upon the cause of the often poor effect of out-patient treatment at the hospitals. Out-patients have to bring their own bottles and corks, and both are old. No amount of healing balm dispensed at the hospital can escape contamination from the cork, and we cannot be surprised if the benefits of the prescription are invalidated. Perhaps the King Edward VII. Fund will appoint a committee to inquire into this important matter.

# A Dublin Branch of the Research Defence Association.

We are glad to learn that a very strong and, so far, very successful effort is being made to establish in Dublin a branch of the Research Defence Association. The Royal Colleges of Physicians and of Surgeons, and the Royal Academy of Medicine in Ireland, have unanimously approved of the formation of such a branch, and, in addition to such purely medical opinion, a very strong body of distinguished laymen have lent their support to the project. Amongst the latter may be mentioned Lord Ashbourne, the Dean of St. Patrick's Cathedral, the Very Rev. William Delaney, S.J., LL.D., Edward Gwynn, F.T.C.D., Lord Iveagh, Professor Joly, F.R.S., the Commander of the Forces in Ireland, Professor Mettam, Lord Monck, Sir John Nutting, the Most Rev. Dr. Peacocke, Archbishop of Dublin, the Earl and Countess of Pembroke, the late Master of the Rolls, Judge Shaw, the Provost of Trinity College, and many others. It is, in our opinion high time that such a branch should be formed, seeing that of the seventeen anti-vivisection societies several have obtained a footing in Dublin and are busily engaged in propagating their doctrines. A striking instance of the harm that can be done when irresponsible people, not overburdened with a sense of the obligation of facts, give their tongues a free run, was mentioned in these columns some few weeks ago. Our readers will remember that just before the annual collection for the Dublin hospitals was made, a lady, at an anti-vivisection meeting, stated that vivisection was performed at almost all the Dublin hospitals, and called on her hearers to refuse subscriptions to them. occurred some couple of months ago, and though the lady has since doubtless learnt that her statements were devoid of even a particle of truth, we are not aware that she has taken any opportunity of correcting or apologising for her statements. It is to combat such people that the branch of the Research Defence Association is to be formed, and we trust that our readers as a body will join it.

# The British Medical Association and its Charter.

The controversy in the British Medical Association arising out of the question of the obtaining of a charter has reached an acute stage, and unless some settlement is speedily arrived at, there is

likelihood of a serious disruption in the Association. There are some indications that the present complicated constitution-inaugurated with such a flourish of trumpets a few years ago-has broken down. In addition, there is considerable difference of opinion as to the true function of the Association. On the one hand, some hold that its work should be mainly scientific, and should centre in the annual meeting as a scientific congress. Others hold that the Association ought to be organised for the defence and promotion of the interests of the profession, due regard being had to local conditions in different parts of the Empire. Between these opposing views it is not easy to find a middle way, and the fact remains that a mass of accumulating wealth remains useless to the profession, both for scientific and political purposes. Again, many members fear that the proposed charter would, if granted, tend to perpetuate the present ineffective working, since it would undoubtedly limit the power of individual members. As we have said, the position is acute, and the combatants show no tendency to come to any agreement.

The New Irish University.

THE troubles of the new Irish University, to which the title "National University of Ireland" has been granted, have begun early in its career, and over a point in itself of trivial importance. The question at issue is the relation of the University curriculum to the Irish language. It is demanded, in somewhat truculent manner, by those who are enthusiastic in the movement for the revival of the Irish tongue, that Irish shall be a compulsory subject in the Arts course, up to the point at which professional specialisation is to be permitted. Some go further, and claim that Irish should be the medium of teaching of other subjects, and that ability to speak Irish should be a necessary qualification for all teaching posts in the University. On the other hand, more cautious persons, including some high academic and ecclesiastical authorities, think that the University would be unduly hampered in its early years if Irish were compulsory. The controversy is being waged with much bitterness in the daily press, and cannot fail to detract attention from really important matters. We trust, however, that the Senate will keep the balance even between contending factions, and will not permit squabbles over details to interfere with their great work of moulding the new University in practical and efficient shape.

### The Cost of Bacteria Beds.

No plan of sewage disposal can be regarded as quite satisfactory unless it furnishes some remunerative bye-product. This ideal has not been attained by modern scientific methods of bacterial treatment, at any rate in the particular means shortly to be adopted at Manchester. The Finance Committee of the Corporation of that city have agreed to the raising of a sum of over £60,000 for the purpose of constructing about ten acres of bacteria beds in one spot, and for the provision of granite to replace clinker almost entirely in twenty-seven acres of second contact beds at another spot. The sewage effluent, thus treated, will be sufficiently purified to satisfy the requirements of the

Mersey and Irwell Joint Committee. The least satisfactory feature of the reports is the terse remark of the Finance Committee to the effect that No income will result from the proposed expenditure." In disposing of the sewage of a great city, it is impossible to lose sight of the fact that a vast potential value is being dealt with, and it is nothing less than a standing reproach to our boasted modern science if all this possible source of wealth is cast into the sea. On the other hand, the community gains by the enhanced purity of the rivers into which the effluent is discharged. It is not a little curious that China, which is certainly not in the forefront of sanitary or any other modern science, restores all the sewage to the soil, and in that way is more conservative of the national wealth.

# PERSONAL.

His Majesty was approached some time ago with a request to open the new pathological department of St. Bartholomew's Hospital, of which he laid the foundation-stone four years ago. The King has now replied that he will endeavour to perform this ceremony about the middle of next month. It is expected that His Majesty will be accompanied by the Queen and Princess Victoria, and considerable ceremony will be observed.

MR. H. H. CLUTTON, F.R.C.S., has been appointed by the King to be Consulting Surgeon to the Osborne Convalescent Hospital for Officers.

PROFESSOR A. R. CUSHNY will open a discussion on "The Action of Alcohol" at a meeting of the Society for the Study of Inebriety on January 12th.

DR. HAROLD R. D. SPITTA, M.D., B.S., D.P.H., has been appointed Bacteriologist to His Majesty's Household.

Dr. F. R. MUTCH, for many years Chairman of the Health Committee of Nottingham, on recently resigning that post, was congratulated on his success in the office by special resolution of the Nottingham Medico-Chirurgical Society.

PROFESSOR VON KORANYI, who has recently retired from practice, has been created by the Hungarian Government an hereditary baron, a distinction which has never befallen a medical man in that country before.

In the Church of St. John the Evangelist there has just been placed a memorial brass to the late President of the Royal College of Physicians of Edinburgh inscribed:—"In loving memory of Charles E. Underhill, M.B., P.R.C.P.E., born March 8th, 1845, departed this life April 24th, 1908."

THE New Year's Honours are confined, as is usual at this period, to the Indian Services, in which we are glad to notice the name of Surgeon-General Bompard, M.D., Director-General of the Indian Medical Service, who becomes a Knight Commander of the Indian Empire.

THE Kaisar-i-Hind Medal for public service in India to Mrs. Surojini Naidu, wife of Surgeon-Capt. M. G. Naidu, Principal Medical Officer, Golconda Brigade, and to Capt. Eugene J. O'Meara, Civil Surgeon of Mizapur.

# A CLINICAL LECTURE

ON

# HÆMOPTYSIS AND EMPHYSEMA.

By LEONARD WILLIAMS, M.D., M.R.C.P.,

Assistant Physician to the Metropolitan Hospital; Physician to the French Hospital in London,

THERE are a great number of people going about who are supposed to be tuberculous, but who are, in point of fact, no more suffering from tubercle than they are suffering from elephantiasis. This woman is a case in point. Her age is 53, an age at which, I admit, tubercle is rather apt to lay hold of those who have a predisposition in that direction. It is the age of decrescence, the "gloaming of life," as the French artistically put it ("age crépusculaire), and it is when the vital forces begin to decline that the powers of resistance against tubercle become depressed.

This patient has been going about with a diagnosis of tubercle upon her for some twelve months, and yet she does not look tuberculous. She is not only well mourished, she is even stout. So far from being anæmic, she is florid. She makes no complaints of night-sweats, and has no tuberculous family history. But she coughs, and not only so, but she has had two or three attacks of hæmoptysis, and it was apparently on this combination that the diagnosis of tubercle was based. Now, it is scarcely necessary for me to insist that hæmoptysis is by no means necessarily tuberculous. The accident owns many causes, amongst them, and one of the commonest, being mitral stenosis. A person with mitral stenosis may very easily have a chronic bronchitis from back pressure on the lungs, so that, to the attacks of hæmoptysis, there is superadded a chronic and distressing cough. Hæmoptysis, even when accompanied by a cough, is therefore by no means necessarily due to tubercle. Another cause of hæmoptysis is high bloodpressure, the blood in this case issuing not from the pulmonary, but from the bronchial vessels, which are branches of the thoracic aorta; and, as you know, a person with high blood-pressure may bleed from anywhere. He may bleed from his bronchial vessels, he may bleed from his nose, from his gastric mucosa, from his kidneys, and even into his retina. But the patient before us has not got any lesion at her mitral valve, nor is her blood-pressure (150 mm. Hg.) sufficiently high to lead us to attach the responsibility for her hæmoptysis upon her bronchial arteries. When you come to examine her you will find that she has an enlarged liver, and you might be led to suppose therefrom that this was a case of hepatic cirrhosis. In the out-patient room people are not very accurate in their statements, and they frequently say that they have coughed up blood when they have vomited it, and vice versa. I think, on the whole, that they prefer to say that they have vomited it, because the vomiting of blood seems to them to be a more heroic proceeding than the mere coughing of it up. However that may be, it is often very difficult to be sure from the patient's description alone whether the blood has issued from the stomach or from the lungs. In this case, happily no ambiguity is possible, for she has been seen by an intelligent observer to cough up three or four teaspoonsful at a time. The enlarged liver, therefore, is evidently not the cause of the hæmor-thage. A little careful questioning of this patient will show that she has been troubled with a cough for several years, that the cough is always worse in winter and better in summer, and that it is of a wheezy, breathless type, very different from the dry, hacking, spasmodic effort which characterises tubercle. An examination of her chest shows that she has, in effect, a very decided degree of emphysema. You will hear all over the upper part of the chest the high-pitched inspiration and the prolonged low-pitched expiration which is so characteristic of the condition. The normal areas of dulness are very difficult to elicit. If you trusted to percussion alone you would imagine that the heart had shrunk to the size of a shilling. The upper border of the liver is impossible to make out; all over both bases behind are the moist, wheezy râles of a chronic bronchitis.

Now what is the relationship between a condition of this kind, which is all too common in out-patient practice and hæmoptysis? If you will consider the pathology of the disease you will, I think, agree that we ought in reality to feel surprised that hæmoptysis does not more often occur. In emphysema the aircells run into one another by the breaking down of their partitions, and in these partitions there are blood-vessels. When this breaking-down occurs, therefore, it ought not to surprise us to find that a rupture of the vessel ensues. And not only so, but when emphysema has been in operation for some years, the amount of room in the lungs in which the blood may circulate is seriously diminished, so that the capillaries which remain are liable to be much overcharged with blood. When we consider their delicate texture it is surely only to be expected that they should occasionally rupture and give rise to hæmoptysis. Emphysema, in fact, especially when complicated with bronchitis, offers the same difficulty to the return of the systemic venous blood as is offered by mitral stenosis. The difference is one of degree only. The block in the one case, it is true, is at the mitral valve; in the other case it is just in front of the pulmonary valve. The difficulty which the right ventricle encounters in getting the blood out of its cavity into the pulmonary capillaries is very much the same as the difficulty encountered by the auricle in getting the blood out of its cavity into the left ventricle. The results in both cases are more or less the same—namely, the production of a back pressure. In the case of mitral stenosis the back pressure shows itself primarily in the lungs, secondarily in the liver, and finally by the ædema of the lower limbs. In the case of emphysema it is the right ventricle which shows the first signs of trouble, and, in order to overcome that trouble, it hypertrophies. The blood which cannot be forced through into the lungs is passed back into the liver, which then acts as a reservoir for the superfluous fluid, and the train of events with which we are familiar in mitral stenosis then becomes repeated—the œdema of the lower limbs and the

ascites.

Now, this being the state of matters, one is led to inquire how it is that hæmoptysis does not more often occur in emphysema. We know that there is a great destruction to the pulmonary capillaries, and we know also that the right ventricle tries to force the unoxygenated blood into the area where it may expect to meet with the vivifying oxygen. The remaining capillaries very soon become stretched, engorged and degenerated, so that here, if anywhere, is a condition eminently favourable to a hæmorrhage. Why does that hæmorrhage not more often occur? Well, the explanation was long ago supplied by Rindfleisch, who showed that wide communications are formed between the pulmonary artery and the pulmonary and bronchial veins, thus relieving the tension in the former vessel and allowing the blood to pass through the lungs without undergoing proper aeration. This want of proper aeration is, of course, the reason of so much distress amongst those who suffer from this disease, and when they live in a climate like our own, more especially in large towns, where at best there is a deficiency of oxygen, and where they are subjected to additional difficulties imposed by fogs, the results of this defiCLINICAL LECTURE.

cient aeration become extreme; the lungs are irritated by their futile attempts to obtain the necessary vapour, and a state of chronic inflammation ensues.

Now, it seems to me that what is to be learned from a case of this kind is, in the first place, to beware of making a diagnosis of tubercle except on sufficient grounds. Hæmoptysis alone does not afford such grounds. With very little care one ought to be able to come to a conclusion as to the cause of an hæmoptysis within a day or two of its occurrence. One of the best means of helping us to a conclusion is the use of the hæmomanometer. In the case of an hæmoptysis where the blood-pressure is low, one certainly has good ground for grave suspicion. The bacillus of tubercle is a vaso-dilator; a tuberculous person almost invariably has a subnormal blood-pressure. Where, on the other hand, the blood-pressure is high, one may always assume that the blood has issued not from the pulmonary, but from the bronchial vessels—that, in fact, the hæmorrhage is due to what Sir Clifford Allbutt calls hyperpieses, to high arterial tension, and not necessarily to any organic disease. Where the blood-pressure is at, or about, the normal level, one may be in the presence either of emphysema or of mitral stenosis. It rather depends upon the stage of either of these diseases what the blood-pressure will be. In not very advanced cases the blood-pressure may be low; in very advanced cases it may be high. But in a general way it is not conspicuously one or the other.

In our endeavours to exclude tubercle as a possible cause, we ought never to neglect the simple expedient of examining the sputa for the bacillus. I need not remind you that a negative result must not be regarded as conclusive; that it is necessary to repeat the examination two or three times; whereas from a positive result there is no appeal. But even where no positive result is obtained, there are other means of coming a conclusion about the existence of commencing tuberculosis. These are two numerous to recount at present, but I have elsewhere (a) considered them in

some detail.

The mistake in diagnosis from which this woman has been suffering has resulted in a considerable aggravation of her difficulties. She has been fed on stimulating foods, and has been given stimulating and tonic medicines. This is, of course, the very reverse of what should have been done for her. Having regard to the fact that she has had more than one attack of hæmoptysis, it looks as if the communications described by Rindfleisch as being generally formed between the pulmonary artery and the pulmonary and bronchial veins, have not been formed in her case, so that the back pressure is obliged to relieve itself by these hæmorrhages. Obviously, therefore, the first thing to do, if you can get your patient to consent, is to perform venæsection. If she will not consent (and not many of them will), you must have recourse to other forms of depletion: mercurial and saline cathartics freely administered and often repeated; a diet which is unattractive and unstimulating must also be insisted upon, for a time, at any rate; and, if it can be managed, she should be removed to some locality where the climate is more equable and the air is purer than it is in the north-east of London.

So far as drugs are concerned, there is not to my mind anything which can compare with the iodide of potassium. This, when combined with a little camphor and a little ammonia in an infusion of senega, acts more helpfully than anything else. There is in this case, of course, another factor which we cannot altogether leave out of account, and that is her age. She is at, or about, the change of life, and we must be careful in giving her medicaments and in prescribing for her regimes, that we do nothing to intensify the difficulties incidental upon that period. Fortunately, everything that I have suggested the present time is not in any degree contra-indicated by such a consideration. They are, indeed, all measures which are proper to the treatment of the menopause. If, however, any difficulties did arise, either as complications or otherwise—difficulties, I mean, of the functional neurotic type—the addition

of some bromide of potassium to her medicine would in all probability speedily dispel them. There is another drug of which I have not yet had sufficient experience to speak with confidence, but of which I may say that it seems to offer considerable advantages, and that is valerianite of menthol. But of all the drugs which are useful at this time, probably none is more efficacious than a really active preparation of ovarian extract.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Professor E. Rimbaud, M.D., Director of the Clinique at the Faculty of Montpellier. Subject: Pneumonia in the Aged."

# CLINICAL LECTURES FOR 1909.

WE have been favoured by promises of Clinical Lectures from the following Hospital Teachers and Post-Graduate Lecturers, to whom we tender our best thanks :-

WM. ALEXANDER, M.D., R.U.I., F.R.C.S., Lecturer on Clinical Medicine, University of Liverpool.

HY. R. ANDREWS, M.D.Lond, M.R.C.P., Assistant Obstet. Physician, London Hospital; Teather of Practical Midwifery, London Hospital Medical School.

Medical School.

A. W. Baker, M.D., B.Ch., F.R.C.S.I., Consulting Dentist, Royal Victoria Eye and Ear Hospital; Dentist, Incorporated Dental Hospital, Ireland.

Sir James Barr. M.D., F.R.C.P.Lond., Physician, Royal Infirmary,

Liverpool.

H. Bennon, M.B., F.R.C.S.I., Surgeon, Royal Victoria Eye and Ear Hospital, Ophthalmic and Aural Surgeon, Royal City of Dublin Hospital.

Hospital.

James Berry, M.B., B.S.Lond., F.R.C.S., Senior Surgeon and Lecturer on Clinical Surgery, Royal Free Hospital.

W. Langdon Brown, M.D.Cantab., M.R.C.P.Lond., Medical Registrar, St. Bartholomew's Hospital, Physician to the Metropolitan Hospital. Harry Campbell, M.D.Lond., F.R.C.P.Lond., Physician to the North-West London Hospital and to the West End Hospital for

North-West London Hospital and to the West End Rospital Services of Surgery in King's College Hospital, Professor of Surgery in King's College. Hospital, Professor of Surgery in King's College. EDMUND CAUTLEY, M.D.Cantab., F.R.C.P.Lond., Physician to the Belgrave Hospitals for Children and to the Metropolitan Hospital. PROF. H. CHAUFFARD, M.D., Physician to the Paris Hospitals. George L. Chiene, M.B.Ed., F.R.C.S., Assistant Surgeon, Royal Infirmary, Edinburgh, Senior Demonstrator of Surgery, University of Edinburgh.

J. Jackson Clarke, M.B.Lond., F.R.C.S., Surgeon to the Royal National Orthopædic Hospital and to the North-West London Hospital.

National Orthopædic Hospital and to the North-West London Hospital.

W. BRUCE CLARKE, M.B.Oxon., F.R.C.S., Surgeon to, and Lecturer on Surgery, St. Bartholomew's Hospital; Examiner in Surgery, Oxford University.

EDRED M. CORNER, B.Sc.Lond., F.R.C.S., Surgeon in Charge of Outpatients, St. Thomas's Hospital, Senior Assistant Surgeon to the Hospital for Sick Children.

M. F. Cox, M.D.R.U.I. (Hon. Causa), F.R.C.P.I., Physician, St. Vincent's Hospital, Dublin; Consulting Physician, National Hospital for Consumption, and Children's Hospital, Dublin.

F. C. CRAWLEY, M.D., F.R.C.S.I., Consulting Oculist, Rotunda Hospital, Dublin, Assistant Surgeon, Royal Victoria Eye and Ear Hospital, Harrison Christ, Rotting Caust, St. Bartholomew's Hospital,

HOSPITAL.

R. J. HALLIDAY CROOM, M.D.Ed., F.R.C.P., Cons, Gynæcologist, Royal Infirmary, Edinburgh; Professor of Midwlfery, University of

Royal Infirmary, Edinburgh; Professor of Midwifery, University of Edinburgh.

Deboye, M.D., Doyen de l'Académie de Medécine, Paris, Physician to the Beaujon Hospital.

M. Dempsey, M.D., F.R.C.P.I., Visiting Physician, Mater Miscricordiæ Hospital, Dublin.

PROY. A. DIETRICH, M.D., Prosector at the West-end Krankenhause, Charlottenburg, Berlin.

J. O'Conor Donelan, M.D., Medical Superintendent of the Richmond District Asylum.

THOS. W. EDEN, M.D.Ed., F.R.C.P.Lond., Obstetrical Physician to Charing Cross Hospital, Surgeon to the Chelsea Hospital for Women.

Jakob Ernheim, M.D., Professor of Clinical Medicine, University of Vienna.

J. HOWELL EVANS, M.D., M.Ch.Oxon, F.R.C.S., Hunterian Professor, Royal College of Surgeons; Surgeon to the Prince of Wales' General Hospital.

Hospital.

M. EWART, M.D.Cantab., F.R.C.P.Lond., Senior Physician to, and

Hospital.

WM. EWART, M.D.Cantab., F.R.C.P.Lond., Senior Physician to, and Joint Lecturer on, Medicine, St. George's Hospital.

ROBT, ALEX, FLEMING, M.D., F.R.C.P., Lecturer on the Principles and Practice of Medicine in the Edinburgh Medical School; Assistant Physician to the Royal Infirmary.

Jas, S. FOWLER, M.D., F.R.C.P., Physician, Edinburgh Royal Hospital for Sick Children.

Geo. A. Gibson, M.D., F.R.C.P., F.R.S.E., Physician to the Edinburgh Royal Infirmary, and Lecturer in Clinical Medicine.

ARTHUR E. GILES, B.Sc.Lond., M.D., F.R.C.S.E., Surgeon, Chelsea Hospital for Women, and to the Prince of Wales' Hospital.

<sup>(</sup>a) "Minor Maladies." Second Edition. 1908. Page 33.

GEO. L. GULLAND, M.D.Ed., F.R.C.P., Assistant Physician to the Royal Infirmary, Edinburgh, Physician to the Victoria Hospital Royal Innumary, Dulliamon, --, for Consumption, . L. GUNN, M.D., F.R.C.S.I., Assistant Surgeon to the Adelaide

Hospital.

N. Sampson Handley, M.D., M.S.Lond., F.R.C.S., Hunterian Professor of Surgery, Royal College of Surgeons; Assistant Surgeon to the Middlesex Hospital.

DE HAVILLAND HALL, M.D., F.R.C.P.Lond., Senior Physician, Westminster Hospital, Consulting Physician to the Brentford, Eltham, and Mottingham Hospital.

JAQUET, M.D., Professor of Therapeutics to the Faculty of Medicine, Paris.

CHARLES R. B. KEETLEY, F.R.C.S.Eng., Senior Surgeon, West London

Hospital.

Hospital.

S. H. Law, M.D., F.R.C.S.I., Throat Surgeon, Adelaide Hospital, Hon. Throat and Ear Surgeon, Stewart Institution, Dublin. John Macintyre, M.B., C.M.Glasg., F.R.M.S., Surgeon for Diseases of the Throat, and Nosc, Glasgow Royal Infirmary.

Elie Metchnikoff, M.D., F.R.S., Professor at the Pasteur Institute, Parts.

ELIE METCHNIKOFF, M.D., F.R.S., Professor at the Pasteur Institute, Paris.

Prof. G. Milian, M.D., Physician to the Paris Hospitals.

Thos. K. Monro, M.D., M.Ch., F.F.P.S.Glas., Physician and Clinical Lecturer, Glasgow Royal Infirmary; Professor of Medicine in St. Mungo's College.

ALEX. MORISON, M.D., F.R.C.P.Lond., Physician, Great Northern Central Hospital.

RUTHERFORD MORISON, M.B.Ed., F.R.C.S.Eng., Senior Surgeon to the Newcastle-on-Tyne Royal Victoria Infirmary; Lecturer on Surgery, University of Durham.

HENRY MORRIS, M.A., M.B.Lond., F.R.C.S., Emeritus Lecturer on Surgery and Consulting Surgeon to Middlesex Hospital; President of the Royal College of Surgeons.

WM. MURRILL, M.D., F.R.C.P.Lond., Physician to the Westminster Hospital.

WM. MURRELL, M.D., F.R.C.P.Lond., Physician to the Wesuminster Hospital.

H. OLIPHANT NICHOLSON, M.D.Aberd., F.R.C.P.Ed., Assistant Physician to the Edinburgh Maternity Hospital.

SIR C. NIXON, BI., M.D., Ex-President R.C.P.I., Vice-Chancellor R.U.I., Senior Physician, Mater Misericordiae Hospital, Professor of Practice of Medicine, Catholic University, Dublin.

SIR LAMBERT H. ORMSBY, M.D., F.R.C.S.I., Senior Surgeon, Meath Hospital and National Children's Hospital, Dublin.

R. W. PHILIP, M.D.Ed., F.R.C.P., Physician to the Royal Victoria Hospital for Consumption, &c.; Senior Assistant Physician to the Edinburgh Royal Infirmary.

PROF. C. POSNER, M.D., Berlin University.

D'ARCY POWER, M.A.OXON., F.R.C.S., Surgeon to, and Lecturer on Surgery at, St. Bartholomew's Hospital, Consulting Surgeon to the Victoria Hospital for Children.

S. PRINGLE, M.B., B.Ch.Dub., F.R.C.S.I., Surgeon, Mercer's Hospital, Dublin.

Dublin.

A. MAITLAND RAMSAY, M.D.Glas., F.F.P.S., Consulting Ophthalmic Surgeon, Glasgow Royal Infirmary, Ophthalmic Inst., Glasgow. Prop. R. Rimbaud, M.D., Director of the Clinique, Montpellier Univer-

sity.

AMAND J. ROUTH, M.D., F.R.C.P.Lond., Obstetrical Physician and Lecturer on Midwifery, Charing Cross Hospital; Consulting Physician, Samaritan Free Hospital for Women.

JAS. W. Russell, M.A., Cantab, M.D., F.R.C.P.Lond., Physician to the Birmingham General Hospital, Consulting Physician to the Midland Ear and Throat Hospital, Consulting Physician to the University of Birmingham; Physician to the Birmingham General Hospital.

University of Birmingham; Physician to the Binningham General Hospital.

Sir Jas. Sawer, M.D., F.R.C.P.Lond., Senior Consulting Physician to Queen's Hospital, Birmingham, and to the Industrial Schools.

A. A. Scot-Skirving, C.M.G., F.R.C.S.E., Assistant Surgeon, Royal Infirmary, Edinburgh.

J. W. Simpson, M.D., F.R.C.P.Ed., Extra-physician, Royal Hospital Stek Children, Edinburgh.

A. J. Smith, M.B., M.Ch., F.R.C.S.I., and L.M.R.C.P.I., Professor of Midwifery and Diseases of Women, Catholic University, Dublin; Gynæcologist, St. Vincent's Hospital.

Sydney Stephenson, M.B., C.M., F.R.C.S.E., Ophth. Surgeon, Evelina Hospital, and the Kensington General Hospital.

W. C. Stevenson, M.D., D.P.H., Assistant Surgeon and X-Rayist, Steevens Hospital, Surgeon, Incorporated Orthopædic Hospital, Dublin.

Steevens Hospital, Surgeon, Incorporated Orthopædic Hospital, Dublin.
GEO. F. Still, M.A.Cantab., M.D., F.R.C.P.Lond., Physician for Diseases of Children, King's College Hospital, Assistant Physician Hospital for Sick Children.
R. A. Stoney, M.B., B.Ch., Surgeon, Royal City of Dublin Hospital.
GEO. A. SUTHERLAND, M.D.Ed., F.R.C.P.Lond., Physician to the North-West London Hospital, Physician to the Paddington Children's Hospital, and to the City Orthopædic Hospital.

James Taylor, M.D.Ed., F.R.C.P.Lond., Physician to the Nationa Hospital for Children's Hospital for Children.

SIR W. J. Thompson, M.D., F.R.C.P.I., Physician in Ordinary to Lord Lieutenant of Ireland; Physician, Jervis Street Hospital, and to the National Hospital for Consumption, Ireland.

NESTOR THRARD, M.D.Lond., F.R.C.P.Lond., Professor of the Principles and Practice of Medicine in King's College, Physician to King's College Hospital, Assistant Surgeon, Royal Victoria Eye and Ear Hospital, late Examiner in Ophthalmology, R.C.S.I.

Arthur Whittield, M.D., F.R.C.P.Lond., Professor of Dermatology in King's College, Physician for Diseases of the Skin to King's College Physician For Diseases of the Skin to King's College Hospital.

Arthur J. Whitting, M.D., M.R.C.P.Lond., Dean offthe N.E. London Poet Cenduate College Development of Wales Hermital

HOSPITAL.
ARTHUR J. WHITING, M.D., M.R.C.P.Lond., Dean offthe N.E. London
Post-Graduate College, Physician to the Prince of Wales Hospital,
and Mount Vernon Hospital.
LEONARD B. WILLIAMS, M.D., M.R.C.P.Lond., Physician to the
French Hospital in London, Assistant Physician to the Metropolitan
Uncertain.

Andrew Wylle, M.D., C.M., Assistant Surgeon, Central London Throat, Nose and Ear Hospital.

# ORIGINAL PAPERS.

# THE OUESTION OF DEMENTIA PRÆCOX.

BY ROBERT JONES, M.D.LOND., F.R.C.P.LOND.

In any province of experience the systematic arrangement of the facts pertaining to it is regarded as one of the most useful instruments in its comprehension and understanding, and for this reason a systematic classification of the various forms of in-sanity has long been accepted as one of the best signs

of psychiatric progress.

The saving of repetition, the avoidance of endless and useless enumeration of single cases, the time saved by their arrangement into kinds or groups, and the assistance to diagnosis, prognosis and treatment, have always justified attempts at a classification of the insanities. So unsatisfactory has every scheme hitherto presented proved itself to be, that it was no new thing to hear murmurs of disapproval with the table presented by a special Statistical Committee of this Association at the annual meeting two years ago. Yet so necessary and helpful is a proper scheme that it at once strikes the merest tyro, and we know that the first self-imposed duty which a fresh medical officer in an asylum performs—and this with the gratification and the excitement of a new discovery—is to invent and evolve a classification of his own, dividing the various forms into groups or kinds into which, in his opinion, any case can with ease find a ready place and label.

It was upon a motion proposed by our President, Dr. Mercier, in 1905, that a committee was appointed to draw up a "Table of Disease," and to report thereon to the Association. In their final summary presented by Dr. Percy Smith are these words:—"In the existing Table 'Stupor and States of Confusion' and 'Primary Dementia' are found, and the committee consider that they are of sufficient clinical importance to justify separate headings, as is recommended. The question of 'Dementia Præcox' was, of course, carefully considered, and the committee did not desire to re-insert this term." The latter statement has undoubtedly been a disappointment to some who appreciate and follow the teachings of Kraepelin, and this special title has certainly received the adherence of many of the younger authors and writers, more particularly in America and in Germany.

It is no easy matter to divide pathological mental states into groups characterised by the possession cf such common characters and marks, that upon a survey any occurring case of insanity can with confidence be therein included. The conjunction of characters that agree and the separation of those which differ do not enable us to classify with facility and confidence diseased forms of every mental constituent, and much care requires to be exercised to use terms exactly and definitely. There is no unanimity even in regard to the classification of the normal mind, for Sir William Hamilton taught that mind could be analysed into three main fundamental constituents, and he considered cognition or thought, feeling, and will or conation to be elemental faculties of the mind, and in Bucknill and Tuke's Insanity, p. 41, edition 1874, a classification of the insanities appears based upon this analysis. It would be correct to state that since the time of Aristotle, who recognised only two main divisions of mind-viz., intellection and conation—until to-day, when there is again a tendency to revert to almost the same dual division, ultimate mental constituents remain a matter of speculation and discussion, and it is not surprising, therefore, that a classification of morbid mental features as observed in insanity should meet with a similar fate.

It is not my object to-day to review the whole systematic arrangement presented in a classification of the insanities, but to deal with one division only, and I would point out that although Esquirol described the so-called dementia præcox under the term quired imbecility," it was not until twenty years or so ago that an attempt was made to group together several more or less allied forms of insanity in the adolescent under the same heading, but under a new name.

I doubt if a more expressive term could be found for this group than was used by Esquirol under "acquired imbecility." It singles out what appears to satisfy the needs of a perfect definition, and supplies the whole connotation of the term. Morel, in France, and Christian also, in his description of "juvenile dementia," anticipated this grouping, which has been further dealt with by Sérieux, but to Kraepelin belongs the distinction of inventing dementia præcox, not as the discovery of a new disease, as some of his disciples urge, but as the grouping together of symptoms which are characterised in the main by progressive deterioration. Whether this grouping is a justifiable one it is the object of this discussion to elicit. It may be observed that the term "dementia præcox" receives no mention in Tuke's Dictionary of Psychological Medicine, and neither Dr. Clouston nor Dr. Savage mention it in their earlier works; moreover, it does not appear in the index to Dr. Bevan Lewis's text-book, yet no one who has read these manuals will deny that all the symptoms descriptive of this condition were not fully realised, accepted and described.

Let us consider for a moment the meaning attributed to the word "dementia," and, so far as I understand the term, it connotes, in the first place, an un-emotional state, for there is neither excitement nor depression, only pronounced inactivity; it is characterised by a negative manifestation of brain action as contrasted with any positive symptoms of excitement. In the second place the term pre-supposes a full development of the mental powers. It is contrasted with amentia, which implies a congenital state, and it is accepted as describing a form of mental disorder characterised by acquired, as compared with congenital enfeeblement of the mental powers. It is not easy to fix any parof the mental powers. It is not easy to fix any par-ticular degree of mental impairment or inactivity as definitely fixing or constituting dementia, but use and custom associate the degree of loss with a depth from which there is usually no recovery, and if there be any one symptom which with confidence can be taken and relied upon as characteristic of dementia, it is loss of memory.

The qualifying "præcox" merely signifies ripe, untimely, before its time; but it has in this particular, as will be seen later, a somewhat extensive application.

In the short printed abstract of what I had intended to say, I made, somewhat didactically, but "with malice aforethought," the statement that stupor was the most prominent symptom, and also that there was a feeling tone of depression in these cases, a condition which was accepted under the very apt definition of melancholia cum stupore.

The presence of stupor is in agreement with the principle laid down by Kraepelin when he added katatonia to the group of general insanities in young people first described by Hecker under the title of hebephrenia, an insanity which he described as beginning ning at the age of puberty, but which has of late received further extension of time from puberty through adolescence and into maturity, and ending in general intellectual enfeeblement. Kraepelin further added a variety of mental aberration characterised by unsystematised and varying delusions described as paranoid insanity. To this class or group the term "dementia præcox" was applied. Kraepelin did no more than group together these three varieties, but many of his pupils allege that he created a new entity, and has thus described what some believe to be a new

It may be well to consider more fully the varieties included under this heading, and firstly hebephrenia, which Kraepelin describes as commencing with hallucinations and delusions, but these tend to disappear; there is jerky mannerism and eccentricity, there is loss of voluntary attention and activity, loss of interest, and apathy, ending, it may be, in speechlessness or "mutism." The cases in this category include those with maniacal excitement, followed by depression, and ending in permanent mental enfeeblement, although it is stated that about 8 per cent. of dementia præcox of this variety recover.

Katatonia (κατα τέινω—to stretch or strain oneself) is applied to a form of insanity characterised by

hallucinations as well as by apathy, loss of interest and of attention, merging into a state of stupor with muscular tension. There is also what is described as "negativism"—refusing to speak, or "mutism," being the best example of this; and here I would venture to ask for a definition of this term. Does "negativism" describe the patient's state to the examiner, or does the term apply to the patient's own mental state and imply loss of consciousness? If the latter, then I would prefer to describe the patient's mental condition as "positivism" rather than "negativism." Cases of this kind are often most resistive, and refuse to do negativism "-refusing to speak, or "mutism," being of this kind are often most resistive, and refuse to do anything requested of them. In addition, there is a anything requested of them. In addition, there is a state of increased susceptibility to suggestion, and such opposite conditions as "negativism" and "suggestibility" pass from one into the other directly, or after impulsive excitement, and thus is seen what is termed "stereotypy," or "stereotyped movements," which are actions repeated purposeiessly and sense-lessly. Although to per cent of these cases recover. lessly. Although 13 per cent. of these cases recover, yet there are no means to judge which cases will recover, or which may lead to different degrees of deterioration.

The third variety, paranoid forms ( $\pi a \rho a \nu \cos - dis$ traught, frenzied) are described as resembling those of chronic delusional insanity, only that the delusions develop more rapidly, and they are less systematised. Hallucinations and delusions of either or both persecution and grandeur occur, and these are believed to be more persistent than in the hebephrenic and katatonic varieties, but they also tend—though less to pass off as mental deterioration progresses. There may be in this variety some katatonic stupor, the pararoid patient being also subject to apathy, loss of interest and activity, and the same "mannerisms" of katatonic patients and the same "stereotypy" are also observed.

It must be acknowledged that there is no hard and fast line to indicate any one of the above groups; the symptoms overlap, and they are interchangeable—for the symptoms of the one are not infrequently observed in the other; indeed, it may be stated that many of

the symptoms are common to all three forms.

Such a classification, with the symptoms of each variety overlapping, fails in one of the fundamental necessities of a logical division, for the varieties are not mutually exclusive. Such an absurd classification would resemble a division of the army into infantry and commissioned officers rather than into cavalry, infantry and artillery.

Can anyone, with experience of the above, and who has a knowledge of practical insanity, for one moment consider these closely-allied varieties to be different kinds or forms of insanity, or that they are limited to adolescence? If this be the case, then it is impossible to include any one class of dementia præcox as "a form of insanity at any one time," such as at the time of observation or of noting, although there are some who propose to diagnose these varieties by so simple an action as a "shake of the hands." If the above classification be a typical one, then I can only say that in Claybury Asylum, with nearly 2,500 patients, there are not more than 5 per 1,000 cases of dementia præcox among the total population; whereas Kraepelin, I believe, considers that the vast majority of the residents in institutions for the insane are cases of this form.

It is not surprising that there is a difficulty in fixing definite types of insanity during the period of youth, for it is one of extreme complexity and variety. The gradual unfolding of the sexual function is accompanied pari passu with an expansion of the emotional life, and during the special epoch of life the mind becomes charged with latent changes, which on the emotional side may well be described as dreamy

longings and per-fervid passions.

During this period, as Dr. Clouston says, intelligence is nascent, ideas are inchoate, and the whole mind is lacking in precision and conscious power. The period of puberty-from 12 or 13 to 15 or 16 years of age—has its special mental formula, and so has the period of adolescence. In both the mental states are different from that in maturity. There is a difference not only of degree, but also of kind, between the several stages of youth and those of manhood, or womanhood, or maturity; and the same causes, or set back, or disturbances give rise, in precisely the same effects, to the same dementia. It is the same shedding of the last acquired and least organised attainment, and the injury to the mind is the same in youth as in subsequent periods of life, the only difference being in its manifestation. In the one period the delusion is tinted with the hopes, the ideals, or the tender sentiments of youth, whereas in adult life it is the result of mature experience.

Pulmonary tuberculosis in the adult lunatic is precisely the same disease as in the stuporose adolescent, although there has been no cough and no expectoration in the latter. Dementia is the same injury in both, only with different manifestations, depending upon the period of life which has its special mental state. Acute rheumatism in adults affects particularly the joints, but in youth the endocardium and the bloodvessels, yet no one considers these to be different diseases requiring a special nomenclature. Ostewarthritis in adults affects the joints generally, yet when it occurs in the young, one joint alone is seen to be affected; still it is precisely the same disease. In just the same way dementia is the same whether affecting young or old, and it needs no special nomenclature.

The grandeur, the false ambition, the mannerisms, and the neologisms of the adolescent lunatic have their roots in the romance, the poetry, and possibly the artistic sensibility of normal adolescence; whilst the ambitions of the adult mono-maniac are the result of his maturity, his past experience, and the effects of his competition for a place in the struggle for existence. The delusions affect the environment as well as the personality of the individual, and he is persecuted, jeered at, or admired as external or internal associations predominate.

The delusions of the hebephrenic or of the paranoid are exactly of the same mechanism as occur in adult life, and Dr. J. S. Bolton has aptly illustrated this by his theory of the inherent neuronic durability, which admits the same injury at varying periods and depending upon the special neuronic resistance. Kraepelin himself accepts this to some degree when he extends the period of this dementia to middle age.

The fact that in adolescence there is great fluctuation of feelings and sentiments accounts for the fantastic delusions on one hand and the languor or stuporose depression on the other. Even in health periods of enthusiastic energy give place to dissatisfaction and introspection; in youth this is especially characteristic. But is there a real difference between the apathy and stupor of katatonia and that observed after any great mental disturbance, such as that seen in the adult after acute attacks of mania, melancholia, folie circulaire, epilepsy, or even general paralysis and other forms of dementia? Indeed, the tendency today is to regard all suspension of psychical operations and all stupors in which the mental processes are more or less in abeyance as coming under the term "katatonia" and being closely allied. I believe that the varieties of what are described as dementia præcox are closely allied, if not identical with what occurs in primary dementia at any period of life, the only difference being due to the different stage of evolution at which the dementia occurs, and at the onset I venture to deny the very existence of such a special form of mental disorder as "dementia præcox."

"There is no new thing under the sun," was observed by Solomon in "Ecclesiastes," but he was probably not so well versed in insanity as his father David, and if his wisdom were appealed to to-day it would draw attention to the neologisms of the modern alienist.

Take, for example, hebephrenia! I wish to know what is the relationship between Hebe, the daughter of Juno and the wife of Hercules, with insanity? Why should this goddess be associated with mental deterioration and decay? Again, in my dictionary, "stereotypy" is stated to be the art of casting by means of a mould, and in another place the art of making stereotype plates!

The term "negativism" does not exist either, but "negativeness" does appear, and is the quality of being negative, a negative being further described as a "picture on glass in which the light parts of the

original are opaque and the dark semi-transparent!" There is no connection suggested between these terms and insanity, although they appear to be the stockin-trade of the alienist of to-day, and I cannot but deplore the coinage of new terms when our own language is so rich in descriptive application.

It would appear from this account of dementia præcox, with its teeming multitude of new names—echopraxia, intra-psychic ataxia, echolalia, psychoanæsthesia, heboid insanity—that such a group of mental disorders never existed before; but what about the condition described by Esquirol as "acute dementia," by Hayes Newington as "anergic stupor," and by another as "apathetic stupor," in cases where the patient is deprived of all manifestations of mental as well as of motor energy? The older classification of "mental stupor" gave the hope of recovery which does and did occur, but the term "dementia" conveys the idea of mental degeneration and irrecovery; yet, as stated, recovery not infrequently occurs. Regarding this point Dr. Clouston states:—"Kraepelin has taken the term 'dementia præcox' and applied it to practically the whole group of my adolescent cases as described by me in 1873, making it cover the curable and incurable. I object strenuously to the word 'dementia' as applied to any recent and curable varieties of mental disease as being confusing and unscientific."

I confess that many cases of mental stupor demonstrate upon careful examination the existence of delusions, and the term "dementia" is hardly applicable to them. I have such a case recently within my memory (photographs exhibited). A man, æt. 25, was admitted under my care with marked stupor and rigidity. He had general anæsthesia, for even deep pin-pricks elicited no response, and yet he felt them, but could not speak or flinch from them owing to the paralysing influence of a great dread. He was mute, cataleptic, and yet he retained full consciousness, for upon emerging from this state his mind was clear, and he repeated every occurrence which he heard around him; conversation was repeated in minute detail, but he was so overpowered with imaginary dread and he was so apprehensive of harm that he could utter no sound at the time. I prefer to call such a case by the old descriptive term "melancholia with stupor," or "melancholia attonita." Another case of melancholia with stupor occurred in the case of a female, æt. 45, and it was typical of the cataleptic variety. I think in neither could the term "dementia præcox" in the other it was not precocious nor untimely. My personal feeling is that for cases up to 45 or 50 this term is too wide in its range, and therefore it is improper to call such cases those of dementia præcox.

term is too wide in its range, and therefore it is improper to call such cases those of dementia præcox. I cannot appreciate the term "para-noid." Why not manoid, melancholoid, paraloid, if the one coinage be justified? I have the same feeling in regard to pseudo-general paralysis. A thing is either what it is or it is not, and such a form of disease is either general paralysis or it is not. A mental state is either paranoia—and Dr. Percy Smith has settled this matter

Again, the characteristic feature of dementia is, as I have already said, loss of memory. The mental reflexes are blunted and inactive, and all interest in former concerns are ended, yet the so-called cases of dementia præcox are most retentive in their memories. After years of asylum residence they can relate with wonderful accuracy what has taken place in their daily lives, and this although they appear to take no pleasure in the society of their kindred, the patient standing about in a state of passive indifference to all environment.

ence to all environment.

Although I animadvert upon Kraepelin's terminology, I am not here to suggest a new scheme of classification, but to criticise the present, and to elicit the opinion of others whose experience and observation of all forms of mental disorders exceed my own. Some who have written upon the subject are delighted that Kraepelin has invented dementia præcox, for they say he has thereby encouraged the alienist to make a diagnosis at once, and not "postpone prophecy until after the event," which nevertheless the use of this term demands.

A terminology which suggests the ultimate termination of a disorder is in my opinion somewhat premature and inapplicable at its inception, more especially if, as in these cases, there is occasional recovery. In an interesting paper by Dr. Drapes (Journal of Mental Science, 1906) upon the unity of all insanity, there are very cogent reasons presented for the exclusion of demential precor and L believe the same view. sion of dementia præcox, and I believe the same view is entertained by Dr. Mercier in a paper printed in the Journal of Mental Science, January, 1905. A further paper by Dr. McConaghey (Journal of Mental Science, April, 1905) proposes the sub-division of adolescent insanity to represent the varieties covered by dementia præcox, a view which has long been adopted dementia præcox, a view which has long been adopted by Dr. Clouston, who gives valuable statistical experience upon the subject. In my experience for the last five years at Claybury, 2,879 young men and women between the ages of 10 and 25 have been received, a slight majority of these being females, and recoveries occurred in 36 per cent. Clearly, therefore, the term "dementia" is out of place. I have included in this group all cases of mania and melancholia, for Kraebelin appears to embrace all forms of insanity of pelin appears to embrace all forms of insanity of adolescence in his group, yet all know the grave prognosis there is in certain stuporose cases, which some of us still term "primary dementia," and which Dr. Savage has so very epigrammatically included in his maxim that it is often \* better to be sixty than sixteen" in regard to the termination of such cases of insanity.

I have been frequently struck by the association and relationship existing between motor and psychic states, and I have witnessed a kind of mental chorea accompanying certain impulsive, motor states. It may not be unlikely that there exists a physiological relation-ship between mental stupor and certain forms of motor spasm or rigidity, just as there is an association between certain muscular paralysis and the mental symptoms of general paralysis, but hitherto it cannot be said that this form of mental enfeeblement in adobe said that this form of mental emechanisms lescence has been illuminated by any definite pathology, and up to the present the researches of Drs. F. W. Mott and J. S. Bolton have approached the subject with the most light.

I cannot conclude without expressing obligations to Dr. Johnstone, of Leeds, who by his excellent and clear translation has brought the valuable researches of Kraepelin within reach of the ordinary student.

Summarising my conclusions:—
(1) There is no definite disease "dementia præcox." The descriptions applied cover almost every possible variety of insanity.

(2) The term "dementia" is inapplicable, because it connotes permanent and irrecoverable loss of mental function.

(3) The application of "dementia" is unsatisfactory to cases in which loss of memory is not a prominent early symptom.

(4) The term does not state whether it is the terminal stage or the stuporose condition which is of primary importance.

(5) The qualifying adjective "præcox" is equivocal, in so far as it leaves it doutbful whether the diseased condition evolves precociously, or whether it is stated to occur in early life or youth. It is therefore a vague and indefinite term, as these symptoms are also known at maturity and even at the menopause, and therefore they should find no place in a scientific or logical classification.

(6) A term which implies a definite entity, and which is with some becoming more accepted as such, should be distinguished by definite pathological findings, which is not the case.

(7) Finally, it is more in harmony with practice and of greater help to diagnosis and treatment, to use, in place of "dementia præcox," the term "adolescent insanity," suitably sub-divided as at present.

DR. HENRY, who is retiring from the position of Medical Officer of Health at Rochdale, has been the recipient of several valuable presentations. He has held the position for 29 years, and will be succeeded by Dr. Anderson, of Aberdeen.

### INTERMENSTRUAL PAIN. (a)

By R. D. PUREFOY, M.D., F.R.C.S.I., Late Master of the Rotunda Hospital.

ONE of the least common and least understood varieties of pain connected with, and dependent on, ovarian functions is that to which Priestley, in 1872, applied the term "intermenstrual." Medical literature does not abound in records of cases in which this pain has been observed; and even in the records furnished us, details are but sparsely given, both as to treatment and its results. In my experience the affection has proved generally rebellious to treatment, and very liable to recurrence. Observers are pretty well agreed that it is an affection of late, rather than of early years, probably most frequently met with between the ages of twenty-five and thirty-five. Its relation to childbearing deserves notice. Those who suffer from it are in most instances sterile, or if mothers have not been pregnant for several years. In some of my cases it occurred for the first time after the conclusion of a pregnancy; in none was it experienced during the very early years of menstrual life.

The majority of those who suffer in this way describe the attack as beginning at a point of time midway between two menstruations; but I have noticed that in a proportion of cases it begins ten, or seven days before menstruation. Relief is generally coincident with the establishment of the menstrual flow; and entire cessation of the pain generally ensues for a variable period. In some instances an observable discharge, either uterine or vaginal, synchronises with the pain; two of my cases illustrate this fact.

Menstruation in these cases does not follow any invariable type, and is sometimes normal in amount; but, in my observation, more generally either scanty or profuse, and attended with pain.

A very interesting question remains—viz., with what lesions of the ovaries or other organs is this affection most frequently associated? On this, as on so many other points connected with our subject, we are compelled to speak somewhat vaguely, as, neither from our own experience nor from that of others, has it been found possible to draw reliable conclusions. I have found it associated with (1) healthy uterus and appendages; (2) endometritis; (3) subinvolution; (4) retroversion. We may at this point advantageously contrast some of the many opinions expressed by others on the subject of this communication. Lawson Tait alludes to this affection thus: - "Since reading Dr. Priestley's paper, I have seen several cases, but have been unable to refer them to any category." In Bland Sutton and Giles' "Gynæcology" we read: -- "Causation and pathology of this affection are as yet obscure; it has been attributed to recurring painful ovulation, independent of menstruation. The more probable explanation is, that it is due to painful efforts on the part of a diseased tube to expel its contents. In the majority of instances it has been found associated with tubal mischief, and especially with that curious condition known as intermittent hydrosalpinx. It is suggested that the uterine congestion which precedes menstruation causes occlusion of the uterine ostium and accumulation of catarrhal contents in the tube; the distension causes pain. When menstruation occurs the congestion is relieved and the uterine ostium of the tube becomes patent, and the tube discharges its contents. Pain is then relieved.'

The authors may claim some credit for their ingenuity in elaborating such a theory; but it is not in accord with clinical facts, though, as we shall

<sup>(</sup>a) Read before the Royal Academy of Medicine in Ireland.

see a little later, Dr. Martin seems inclined to accept this view. When writing of ovarian dysmenorrhæa. the late Dr. Thomas observes :- "One very curious phenomenon which now and then marks these cases is the occurrence of intermenstrual pain. At times this occurs with wonderful regularity on a certain day. In one case in my experience it occurred on the ninth day after menstruation had ceased, in another on the fourteenth, and in a third it com-menced one week after the menstrual act and continued for five or six days." Fehling explains intermenstrual pain as a normal ovulation between two menstrual periods, On this point Macnaughton-Jones remarks: - "How common such pain is every gynæcologist is aware, and the relief of this symptom as well as the pain of ordinary menstruation by treatment of the ovaries, or their massage, is explained by the consequent changes of the relative position of the adnexa and uterus.

12 THE MEDICAL PRESS.

With every respect for the learned writer, I find myself unable to accept as accurate the statement "that such pain is common," or that the alteration of the relative position of the uterus and the adnexa has the effect attributed to it. Hermann alludes to this condition under the title, "intermediate dysmenorrhœa," and favours the notion that it depends on the regular monthly maturation of an ovum, the process being painful because the outer part of the ovary is thickened, either from fibrous growth or organised inflammatory lymph. For treatment, he suggests that we should treat the disease of the ovary on which it depends. Christopher Martin writes:—"The pain is regular in its onset, always fourteen days before the next period; it is violent and occurs in paroxysms, and lasts for three or four It is accompanied by a watery discharge from the uterus; in a few cases the discharge is hæmorrhagic, but scanty, so that there is an abortive period in the middle of each interval. On examination, the pelvic organ may be found normal, but there are usually distinct signs of chronic inflammation in the tubes or ovaries. In a considerable number of cases the condition of hydrosalpinx has been found associated with intermenstrual pain, and by most authorities is believed to be the cause thereof."

I have never seen a case in which this pain was "violent and paroxysmal," though this would be easily understood if it were associated with hydrosalpinx, which, in my experience, is by no means common. Intermenstrual pain is generally, though not always, referred to either ovarian region, and sometimes to the right and left sides alternately. In two cases recently under my care it was felt in the breasts alone.

Brief records of some of my cases are as

Case No. 1.—Patient, æt. 34, unmarried, rather delicate from childhood; menstruation came on rather late and has become increasingly painful. At present presents most of the features of wellmarked ovarian dysmenorrhœa; severe pain in groins and tenderness of breasts a few days before the flow appears, attended sometimes with headache and retching. For the past few years severe intermenstrual pain, beginning fourteen days after the first day of preceding illness; no disease of uterus or ovaries discoverable.

Case No. 2.-Patient, æt. 34, healthy aspect, fifteen years married, nine children. About eighteen months after last confinement began to suffer from intermenstrual pain in left side, extending into groin. Examination disclosed nothing more than slight enlargement of uterus and endometritis; no disease of appendages was detected. This patient suffered in a marked degree from

dyspepsia and constipation, for the relief of which she underwent treatment during some months, together, with occasional uterine treatment, and for a time complete relief from the intermenstrual pain was obtained. Amongst other drugs perseveringly used were iodide of potassium and bichloride of mercury. In this case the intermenstrual pain is attended by discharge.

Case No. 3.-Patient, æt. 35, three years married. During her first and only pregnancy, which ended eighteen months ago, was in poor health and her urine was highly albuminous. Uterus somewhat enlarged; os externum small and circular, affording no evidence whatever of parturition having occurred. Some glairy discharge is constantly present; abdominal walls very thick; appendages not distinctly felt. Has suffered much from intermenstrual pain, especially during the last year. Treatment in this case has been followed by much relief, the intermenstrual pain especially having nearly ceased. In my opinion, aspirin contributed to this satisfactory

Case No. 4.-Patient, unmarried, æt. 27; complains much of failing health, loss of weight and energy, and frequent attacks of nausea, especially at meal-time. Menstruation is painful, and a vaginal examination shows that the uterus is low in pelvis and retroverted. In this case the intermenstrual pain is in the breasts, not in the pelvis. Under treatment, local and constitutional, the dysmenorrhœa and nausea were completely cured, and the mammary distress alleviated.

Case No. 5 .- Patient, æt. 41, nine years married. Some months before marriage, following exposure to cold, irregular menstruation and frequent sick headaches were a source of much trouble, and about the same time patient began to suffer from pain and swelling in both breasts, starting a fortnight

before each illness.

Case No. 6 .- Patient, æt. 33, single, troubled with frequent micturition and menstruation, discharge returning every two weeks, attended with swelling and tenderness of breasts. Pelvic conditions, vulvitis and vaginitis; uterus retroverted and adherent; much evidence of endometritis. Several days after each menstruation severe crampy pain is experienced in lower belly, accompanied by red discharge. Treatment afforded but little relief.

Case No. 7 .- Patient, æt. 29, four years married, two children. Suffers much pain in belly, discomfort and vomiting between menstruation; the pain begins on the 20th and lasts till the 28th of each month. Local conditions: laceration and ectropion of cervix, uterine cavity  $3\frac{1}{2}$  inches. Treatment brought about a healthy state of the uterus, but very little diminution of the intermenstrual pain.

Case No. 8 .- Patient, æt. 26, three years married, childless. Chief trouble is headache, beginning one week after, and lasting till one week before men-struation. Nothing worth noting in the condition

of the pelvic organs.

It may be readily understood from the foregoing that treatment must be varied, directed to the removal, if possible, of any ascertained morbid conditions, and, in their absence (and, indeed, in every case), to the improvement of the general health. In a few cases, which have proved not amenable to other measures, the removal of one, or both, ovaries, has been practised, but with results so variable and inconstant that it cannot be advised in future, unless as a last and desperate resource We should, I think, refrain as much as possible from the exhibition of narcotics, especially opium. Perhaps an exception may be made in favour of Indian hemp, especially if given in pill with quinine. It will be well to bear in mind the varying strength

of different samples of this drug, and, in order to avoid the production of sometimes alarming constitutional disturbance, to instruct our patient to take it always shortly after food. Recently I have given aspirin once or twice in the day with encouraging results. Arsenic, too, deserves to be remembered amongst the remedies likely to be of any service.

In my opinion, intermenstrual pain is dependent on, and caused by, the maturation of a Graafian follicle in an ovary itself in a pathological condition, and generally surrounded by structures which have been implicated in an inflammatory process.

Treatment, to be effectual in giving relief should be, constitutional, to improve the general health, and, local, to relieve, as far as may be done, the associated diseased conditions.

# "STITCHES."

# By Prof. HENRI BARTH, M.D., Fhysician to the Necker Hospital, Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

By "stitch" I mean a special kind of pain in the side that occurs as a symptom of certain acute pleuro-pulmonary affections, and constitutes an important factor in the production of dyspnœa, since it is intensified in proportion to the depth of respiration, until it becomes well-nigh intolerable.

Either suddenly or gradually, a person who may either be in good health or has been suffering from some chest affection is seized with spontaneous, intense, strictly localised pain, situated either in the mammary region or at the angle of the shoulder-blade behind. This pain is sometimes dull and continuous, in others lancinating or stabbing, is increased by coughing, deep inspiration and movements of the trunk muscles.

This peculiar pain is due to irritation of one or several sub-pleural nerve fibres by inflammation of the enveloping serous membrane. It is, therefore, essentially a symptom of pleuritis, and, like the latter, may be associated with any affection that involves the pleura or the cortical layers of the lung.

In acute pneumonia the pain in the side is usually present from the onset, except in cases where the phlegmasia has started in the depth of a lobe, in which event it may only supervene at or towards the fifth day, at a time when auscultatory signs reveal the extension of the morbid process towards the surface. This pain is dull, aching, and constant. Its point of maximum intensity is in the sub-mammary region of one or other side. When violent, the patient instinctively holds his breath, and fixes the thorax by inclining the trunk towards the affected side. The voice and cough are jerky, and the efforts required to eject the sputum make

the patient cry out with pain.

This pain rarely lasts for more than forty-eight hours, after which it gradually subsides. Its persistence after the sixth day, or its recurrence after defervescence, is almost always indicative of the

supervention of a secondary pleurisy.

Pain in the side in the course of an attack of bronchitis, unless due to pleurodynia provoked by the cough, may be caused by a focus of broncho-pneumonia extending towards the surface of the lung, and careful auscultation over the seat of the pain will often enable us to detect the physical signs confirming this supposition.

Pneumothorax, especially in the septic form, is ushered in by sudden, very severe, lancinating pain on one side of the thorax, which the patient describes as "stabbing"; it may be so intense as to paralyse the costal movements of respiration, giving rise to very pronounced dyspnœa, especially in cases where the healthy pleura, being quite free from adhesions, offers no obstacle to the complete retraction of the lung, or when the valve-like opening in the lung favours the accumulation of air in the pleural cavity.

Pain in the side is rarely absent in sero-fibrinous pleurisy, and, as a rule, it comes on early. It is generally of a dull aching kind, is intensified by coughing, and subsides as soon as the layers of inflamed pleura become separated by effusion, giving place to a feeling of distension, merging into thoracic fulness when the quantity of fluid increases to such an extent as to exert compression on the subjacent lung and displace the neighbouring viscera. It may once again become sharp when the fluid has been re-absorbed and the false memberanes are being organised into adhesions, and it may possibly persist for months while retraction is going on.

In diaphragramatic pleurisy the pain in the side is due to irritation of the terminal fibres of the phrenic nerve, and is felt along the margin of the left false ribs in front. Pressure on this spot (Mussy's "diaphragmatic button") renders it so severe as to determine symptoms of impending suffocation. In these cases, too, we often meet with spontaneous pain in front of the scaleni on the same side and along the corresponding margin of the sternum. The diaphragm on the affected side

is paralysed and immobile.

In purulent pleurisy, especially in the septic variety, associated with gangrene of the pleura, the pain in the side is of intolerable severity. It may be felt either in front or behind, but it is always strictly localised. The slightest pressure, even that of simple percussion, makes the patient cry out with pain. In contrast with these hyperacute forms is the dull aching pain sometimes met with in tuberculous patients in presence of limited dry pleurisy. The pain is situated at the apices under the shoulder-blade, or, less frequently, under the clavicle. It is of variable intensity, and appears to be influenced by damp cold, which often leads it to be diagnosed as "rheumatic."

A more definite and fixed pain in a tuberculous subject usually indicates the formation of another focus of disease. In these cases, to which Sabourin has recently called attention, the pain in the side coincides with remarkable accuracy with a spot of the pulmonary parenchyma, in which crepitation and blowing sounds may be heard. This may be in the armpit or in the back, generally in close

proximity to an interlobar fossure.

The epigastric spot recently described by Dr. De Brun, of Beyrouth, in pulmonary emphysema, is, according to this observer, consequent upon dilatation of the right heart, and is also met with in mitral affections at the stage of threatening asystole. The pain in question, which was noted in forty-five out of sixty-eight patients suffering from emphysema, is usually situated at the upper part of the xiphoid region. The pain is described as a distressing sensation of weight or epigrastric pressure, sometimes radiating towards the lower dorsal region. It is persistent and is intimately associated with the dyspnœa, becoming worse under the influence of causes that tend to exaggerate the latter and characterised by frequent nocturnal exacerbations. Pressure renders it unbearable. It is always accompanied by hypertrophy of the right heart and visible epigastric pulsation. It is relieved by morphia and the iodides.

False Pains in the Side.—Certain other forms of thoracic pain may be mistaken for "stitch," in consequence of their interference with respiration. They present certain special features, which, in addition to the absence, as shown by auscultation,

of any other sign of pleuro-pulmonary disease, enable us, as a rule, to recognise their nature.

We may mention en passant intercostal neuralgia, recognisable by its half-girdle distribution, running along one or more of the intercostal spaces, the existence of the pain-spots described by Valleix, its paroxysmal aspect, and the zona that sometimes accompanies and explains it. Pleurodynia, which is often consequent upon direct chill, may be identified by its being situated only in the walls, and especially in the muscles, by its vague and mobile character, by the relief afforded by massage and counterirritation. The pain of atheromatous chronic aortitis affects the character of a sub-sternal bar, which is not manifestly affected by the respiratory movements, but is aggravated by the least muscular effort, radiating into the shoulder and left arm. Lastly, the distension pain of gastro-colic, usually referred by patients to the region of the heart, is distinguished by its sudden onset, its acuteness, by the anxiety it inspires, and by its equally rapid subsidence after the eructation of gas or intestinal borborygmi.

# CLINICAL RECORDS.

# NECROSIS OF THE SPLEEN FROM THROMBOSIS OF THE SPLENIC ARTERY.

By F. PARKES WEBER, M.D., F.R.C.P.,

Senior Physician to the German Hospital, London.

The patient was a thin, shrivelled-looking woman, act. 75, who died at the German Hospital in November, 1908, from advanced pulmonary tuberculosis. The pulmonary disease was accompanied by occasional moderate fever, but there was no cough or expectoration. There was no evidence of cardiac disease. The urine contained a trace of albumin. The spleen could not be felt during life, and there were no symptoms drawing attention to that organ. The lower part of the right lobe of the liver extended far down on the right side of the abdomen, so as to simulate an abdominal tumour.

At the necropsy it was found that this lower part of the liver was separated from the upper part by a moderate transverse constriction of the "tight-lacing" kind. Though the liver extended so far downwards, the weight of the organ was only 45 ounces. The gall-bladder contained bile and several small black calculi. The kidneys showed slight interstitial fibrosis. The heart appeared free from disease. The abdominal aorta and its branches showed much atheromatous change.

The spleen (weight about 12 ounces) was somewhat enlarged and hard, and of a peculiar brownish colour on section. It contained some whitish and two or three red, infarct-shaped patches. The splenic artery and its branches were thickened and calcified, and completely occluded by recent dark thrombus.

Microscopic sections of several pieces of the spleen (for most of which I am indebted to Dr. Chapuis) showed that the white areas were not the only necrotic portions, but that the substance of the whole organ, with the exception of the alreadymentioned red patches, had undergone a similar degeneration. In most parts the nuclei of all the cells, excepting the lymphocytes of the Malpighian follicles (illustrating the relatively great resistance of the lymphocytes to necrotic processes), had disappeared (karyolysis). In some parts, especially near the splenic capsule, another form of degeneration with karyorrhexis was to be observed. The

arteries were much diseased, and many of the intrasplenic blood-vessels were thrombosed.

The increase in the size of the spleen was evidently the indirect result of the chronic disease of the splenic artery and its branches without and within the organ, whilst the recent complete occlusion of the main arterial trunk had practically converted the whole organ into one big infarct. The necrosis of the different portions of the organ was evidently not all of the same date, some of the arterial divisions having evidently been occluded before the others, but it is not quite clear why in the two or three sharply-defined (infarct-shaped) red patches necrosis had apparently not yet occurred. If septic changes had continued to remain absent, and if the patient had lived long enough, the spleen would probably have been ultimately replaced by fibrous tissue, which would have gradually contracted like the scar following an ordinary infarct.

In the literature at hand on diseases of the spleen I have come across no reference to any case quite similar to the present one, but it is well-known that non-septic necrosis and atrophy may follow torsion of the pedicle of a "wandering" spleen, when the torsion is of sufficient degree to cause vascular ccclusion. In Professor M. Litten's account of "Diseases of the Spleen" (German edition, Vienna, 1898, page 32), in Nothnagel's great "System," the author points out that a "wandering" spleen may, by torsion of its pedicle, not only become necrotic and atrophied, but may even, by gradual atrophy of its pedicle (with, perhaps, some slight final traumatism), come to lie free in the abdomen. Dr. J. C. G. Ledingham kindly informs me that he remembers having been present at a necropsy apparently illustrating this sequence of events, for a shrivelled, degenerated spleen was found lying unattached in the peritoneal cavity.

# OPERATING THEATRES.

GUY'S HOSPITAL.

LATERAL SINUS THROMBOSIS AND CEREBRAL ABSCESS.—MR. R. P. ROWLANDS operated on a boy, æt. 17, who had been admitted for pyrexia supposed to be due to typhoid. Shortly after admission the patient had a rigor, and, on inquiry, it was discovered he had had two others shortly before admission. There was a slight discharge from the right ear, and he was tender in the upper part of the neck on the same side. Lateral thrombosis secondary to mastoid disease was the diagnosis. The mastoid antrum was opened, and the lateral sinus explored. Lateral sinus thrombosis was discovered. The horizontal part of the sinus was plugged, and the internal jugular vein tied close to the clavicle. The thrombosis was early, and there was pus in the bony canal surrounding the vein. The pus was evacuated, and the horizontal part of the sinus plugged in order to prevent blood flowing over the septic clot in the sinus. The wound was drained with gauze. Mr. Rowlands said that in lateral sinus thrombosis there was no complete obstruction, and that the dissemination of the infection was due to this fact, septic emboli being carried to the lungs and elsewhere by the stream of blood passing over the infective clot

septic emboli being carried to the lungs and elsewhere by the stream of blood passing over the infective clot. The boy progressed favourably for a few days, but at the end of a week the mental condition became a little blurred, and the temperature, which had come down to normal, went up again to 103°. His manner and actions were strange and unreasonable, though not violent; he wasted rapidly, and was constipated. The right pupil became smaller than the left, and there was early optic neuritis. It was therefore concluded that there was a temporo-sphenoidal abscess. The wound was re-opened, and the roof of the antrum removed with a small piece of the outer wall of the squamous portion of the temporal. The brain was explored with a needle, which was passed into the brain in several

directions until pus was found low down. A knife was passed along the needle into the cavity, and a drainage tube inserted and sewn to the skin.

Mr. Rowlands said that the interesting points of the case were the importance of rigors in the diagnosis of lateral sinus thrombosis when associated with the slightest discharge from the ear. The tenderness along the upper part of the internal jugular vein was also of great diagnostic importance, and also the pain elicited by percussion of the mastoid process. The mortality of lateral sinus thrombosis is, he remarked, very great unless an early operation is performed, in fact, immediately after the condition is reasonably suspected. It is of paramount importance, he considered, to block the central part of the lateral sinus so as to prevent embolic infection. For the same reason the internal jugular vein is tied low down in the neck. It is well to leave a plug in the sinus for about four days, at this period little or no bleeding occurs on its removal; only in the event of any hæmorrhage occurring, a fresh plug would be introduced. Mr. Row-lands pointed out that the tympanum was left un-touched (except for drainage through the mastoid) in order to save the hearing as much as possible. The mastoid cells and the outer wall of the mastoid process, of course, were removed freely. He pointed out that the plug is originally placed between the fibrous covering of the sinus and the bone (extra durally) so as to occlude the former without risk of spreading septic thrombosis centrally into the other cranial sinuses. With reference to the diagnosis of the early temporo-sphenoidal abscess, he said one had to rely mainly on the curious and characteristic mental condition, the high temperature and the early optic neuritis, the wasting and the constipation; there was no vomiting and no headache. To explore this region the simplest and best plan is to enlarge the wound in the mastoid bone upwards and slightly forwards so as to expose the dura mater in the outer floor of the middle fossa. The advantages of this method are that excellent drainage is provided and the abscess is more easily and certainly found, because it is always in close proximity to the diseased bone. Besides no troublesome gap is left in the skull. He considered it to be of great importance to sew the tube to the edges of the skin wound so that it may not slip out, as its re-introduction would be difficult and perilous. The tube should not be disturbed for three days, so that a good passage may be established along the track, thus rendering re-introduction easy and without danger. It is important also to continue the drainage for a sufficient length of time in order to obviate any chances of re-collection of pus in the abscess cavity.

The patient's convalescence was uninterrupted. He had a chronic sinus for some time, leading down to the mastoid. The drainage tube into the brain was discontinued after ten days, and the patient left the hospital five weeks after operation. Mr. Rowlands has seen him several times since in the out-patient room; his progress has been good, the wounds were healed, there was no discharge from the ear, and the hearing of the right ear is fair.

# TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, DECEMBER 11TH, 1908.

The President, Dr. E. HASTINGS TWEEDY, in the Chair.

EXHIBITS.

A MODIFICATION OF BANDL'S HOLLOW SOUND.

DR. WILSON exhibited a modification of Bandl's hollow sound, which did away with the difficulty in the mechanical cleaning of the instrument.

The President considered the exhibit a great improvement on any other Bandl's sound that he had

Dr. FITZGIBBON thought the instrument as modified would much more serviceably carry and apply whatever fluid was used.

Dr. ASHE said he had tried the instrument on 200 women last year, and found it of use.

Dr. Tweedy exhibited specimens of

(a) HYPERNEPHROMA; (b) TUMOURS FROM A CASE OF RECURRENT FIBROIDS.

(a) A. M., æt. 57, widow; 15-para; last pregnancy 13 years ago.

History.—Has noticed tumour in side for three years;

increased latterly in size.

Physical Signs.—A large cystic tumour, very fixed, extending on left side from pubic brim to kidney region. A cord-like mass felt through rectum was diagnosed as ovarian pedicle, and a diagnosis of probable ovarian cyst made. On opening the abdomen a large retroperitoneal cyst came into view. The great omentum surrounded it on all sides. Numerous adhesions to intestines. The omentum was with difficulty separated, and enormous vessels tied. During the process the tumour ruptured, and about two pints of pus escaped. The pedicle was reached, and the tumour was discovered to be renal in origin. Pedicle was secured with catgut, and the ureter divided and stitched into abdominal wall. A gauze wick was in serted to provide an escape for oozing. Uninterrupted recovery.

Hypernephroma was a somewhat rare tumour. first case in which a kidney was removed, a diagnosis of ovarian cyst having been made, was temoved, a diagnosis of ovarian cyst having been made, was by the late Mr. Lawson Tait, and everyone was amazed at his statement that he believed it was an ovarian tumour until the pathologist told him it was a kidney.

(b) February 17th, 1908.—M. A., æt. 70.

History.-For past two years has bled on and off. In June, 1907, bleeding got worse, and has continued ever since. Lately has become more of a discharge.

Physical Signs.—Sloughing polypus protruding from vagina.

Operation.—Large amount of sloughing material

taken away by vagina.

Pathological Reports-Macroscopic.—(1) White, rough mass, size of hazel nut; myoma or malignant. (2) White, friable masses; necrosed myomata. (3) Torn masses of fibroids; purulent exudate. Microscopic.—
(1) Highly cellular tissue, with blood vessels. Cells show some irregularity in size, but are not decidedly

malignant. (2) Necrotic myoma.

November 10th, 1908.—Complaint.—Passing fleshylooking masses by vagina from time to time.

Physical Signs.—Broad pedicled polypus attached to

Diagnosis.—Polypus; malignant?

Operation.—Amputation by vagina.

Pathological Report — Macroscopic. — Soft, friable masses. Microscopic.—Necrosed fibrous and muscle tissue.

This tumour was found in the vagina of a lady, æt. 71. She had come to him ten years ago, stating that the late Dr. Mason had removed a number of myomata from her. She at this time suffered from a vaginal polypus, which came away without operative help. At intervals since this she had returned to him bringing myomas which had passed from her. In May last he removed an enormous sloughing mass, which Dr. Rowlette said was possibly malignant, though he was inclined to think it was a myoma. She went away in good health, but came back about a fortnight ago very ill, when he removed a similar mass. Again Dr. Rowlette reported it to be a myoma. The woman's uterus was not bigger than a shut thumb, and there

was no myoma in it, so far as he could now ascertain.

Dr. Rowlette said he had seen two or three hypernephromas shown by others. The tumour was usually situated apparently in the kidney, and was supposed to originate from the adrenal body. The structural connection was not at all clear in most cases, but, from the histology of the tumour, it more closely resembled, where the type was well retained, the structure of the adrenal body than the kidney itself. Degeneration was fairly common in the tumour, but in the few instances that he had seen he had not observed so much de-

generation as in the case before them. Microscopically the material resembled pus, though they were unable to isolate any micro-organism. It was difficult to obtain good microscopic section in the case of the recurrent fibroids, as the material from the tumours was always proportion of semi-proportion but he could be applied to the recurrent fibroids. always necrotic or semi-necrotic, but he could come to no other opinion than that it was necrosed fibromuscular tissue. He found nothing to suggest any malignant change.

16 THE MEDICAL PRESS.

Dr. Pureroy recalled cases in his own experience showing that what appeared to be an ovarian cyst might prove to be renal. He also had had the experience of repeatedly removing a large sloughing mass, which was apparently ordinary fibro-myoma. He thought it was only after the third operation that they discovered evidence of sarcoma. Ultimately he performed hysterectomy, but the patient did not recover.

The PRESIDENT, in reply, said the patient was never in a condition that would enable him to remove the uterus. She never came to him until she was at the point of death. His object then was to remove the mass at once, and he was always convinced that it was the last time he would see her.

Dr. R. D. Purefor, formerly Master of the Rotunda

Hospital, read a paper on

#### INTERMENSTRUAL PAIN.

which will be found in another column under the heading of "Original Papers," page II.

Dr. FitzGibbon also read a paper on the same subject for Dr. Spencer Sheill, which will appear in these columns next week.

In the discussion that followed, Dr. WILSON remarked that he thought that where there were evident local lesions, which could be corrected, with the result that the pain ceased, it hardly came under the head of intermenstrual pain; neither did cases in which congestion of the ovaries was relieved by the loss of blood at the period. The difficulty of treating cases of pain that came on a definite number of days after a menstrual period, and ceased a definite number of days before a period, was very great, and although of days octobe a period, was telly given, and annually the drugs mentioned might give relief, it was a matter of considerable doubt as to what the condition really

Dr. Ashe considered the condition was probably due to some form of toxemia arising from an excess of internal secretion of the ovary.

Dr. NEILL remarked that salicylate of menthol had

recently been advised for relief of pain.

Dr. FITZGIBBON said that in speaking of intermenstrual pain there was a tendency to mix up a variety of different diseases. They should keep in mind that the pain should be one which occurred at a fixed time between the periods, and in which there was no definite organic disease. The ignorance which existed as to ovulation made it difficult to say certainly that it was congestion of the ovary that caused the pain, but he expected that Dr. Sheill's suggestion of circulatory treatment would improve the condition.

Dr. Katherine Maguire said she did not find the

condition common in an excessive degree. She found aspirin rather a dangerous drug, as far as its gastric symptoms were concerned, though it certainly relieved She found phenacetin to do good. If ammonol or antikamnia were given, they should be given after food, and with tea or coffee, which neutralised their effects. She regarded both drugs as dangerous be-

cause they were compounds of antifebrin.

The President said that women suffered from constipation and congestion of the pelvic organs, and he believed that this congestion would be relieved by free purging better than by the drugs mentioned. He thought that in most cases, not due to constipation or neurasthenia, they would find some disease of the tubes which might give no evidence of their condition to the examining finger.

Dr. Purefoy, in reply, said he agreed with Dr.

FitzGibbon's limitation of cases, but such typical cases were rare. He was very sparing in his pre-scription of drugs, and considered that anything like repeated use of the coal-tar remedies was greatly to be deprecated.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

MEETING HELD ON FRIDAY, DECEMBER 18TH, 1908.

The President, Dr. A. J. WALLACE (Liverpool), in the Chair.

EXHIBITION OF SPECIMENS AND CASES.

DR. Donald (Manchester) showed a broad ligament cyst of doubtful origin, having a squamouscelled lining.

Dr. Fitzgerald exhibited a specimen of early unruptured tubal gestation.

Dr. Lloyd Roberts (Manchester) showed (1) a fibroid polyp of the uterus, undergoing extrusion, removed from a patient, æt. 39, primipara, who suffered from menorrhagia. Angiomatous changes in its structure were demonstrated microscopically. (2) A uterine fibroid undergoing cystic degeneration.

Miss Frances Ives (Liverpool) communicated three cases of ectopic gestation, and showed the specimens and microscopical sections. (1) An early unruptured tubal pregnancy occurring in a young lady, married 15 months, who had an attack of pelvic pain 14 days after a normal menstrual period. The pain recurred ten days later, and per vaginam the right ovary was the size of an orange, and some thickening could be detected in the left Fallopian tube. Abdominal section revealed a patent left tube, in the ampullary portion of which a plum-coloured swelling, \(\frac{1}{2}\) in. in diameter, was situated. The left ovary was also cystic, and was removed with the pregnant tube. The right ovary formed the larger cyst, but partial resection was possible, and healthy ovarian tissue was left near Sections from the middle of the swelling showed the intra-muscular site of the ovum. (2) Serial sections of the Fallopian tube in a case of peri-tubal hæmatocele removed from a multipara who had profuse irregular bleeding following a scanty period at the usual time. The undilated tube was found closely associated with a mass of blood clot at its fimbriated end. It was permeable throughout, except at one spot, where the lumen was encroached upon by a small mass of organising fibrin and old blood clot, due to either a tubal mole nearly absorbed or to an incomplete tubal abortion. No traces of chorionic villi could be seen. (3) A tubal mole without hæmatocele occurring in a married woman æt. 34. II.-para, in whom six weeks' amenorrhœa was followed by three weeks' moderate hæmorrhage.

Dr. W. K. Walls (Manchester) brought forward a case of rupture of the uterus. The patient, æt. 32, was admitted to St. Mary's Hospital, following an abortion, in the treatment of which dilatation of the cervix by tents and the evacuation of the uterus had been performed by her doctor. Several feet of small intestine, separated from its mesentery, protruded from the vulva. Laparotomy and end-to-end anastomosis was performed, but death occurred suddenly on the fifth day. At the autopsy primary healing of the bowel had taken place.

Dr. Grimsdale (Liverpool) recorded the case of a patient, married at the age of 42, who consulted him a year afterwards on account of "dyspareunia." The vagina would only admit the little finger, and that with some difficulty. Dilatation of the vagina was suggested, but was not carried out. Nine months later she returned complaining of symptoms suggesting pregnancy, and on examination it was found that she was three months pregnant, the vagina now admitting the index finger with considerable difficulty. On several occasions during the pregnancy vaginal examinations were made, but the tissues continued to be very rigid. After much consideration it was recom-mended that a Cæsarean section would offer the best prospect to the mother and child. This was accord-

ingly done at the full term, with the best result.

Dr. A. J. WALLACE delivered his Presidential Address, in which were reviewed briefly the recent

tendencies to the adoption of

CONSERVATIVE METHODS OF TREATMENT IN CASES OF PELVIC INFLAMMATORY DISEASE IN THE FEMALE.

Particular reference was made to the "Belastung" therapy and to the application of Bier's hyperæmic treatment to gynæcological cases, and Hörrmann's account of the striking results obtained in J. A. Amann's Klinik was referred to in some detail. While admitting the favourable influence exercised by hot-air hyperæmia in non-suppurative disease, it was necessary to recognise that the evidence up to the present was decidedly in favour of surgical interference in pus cases. After animadverting on the neglect on the part of the gynæcologist to take up the question of the prophylaxis of pelvic inflammatory disease, and reference to the measures that were being taken in other countries, the Address dealt with the relations between general surgery, obstetrics and gynæcology.

# CORRESPONDENCE.

### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

# FRANCE.

Paris, Jan. 3rd, 1909.

CUTANEOUS DRAINAGE.

THE ideal method for removing cedema is that which consists in eliminating by the kidneys the liquid effused into the skin and the cellular tissue: massage, milk diet, and digitalis in cardiac disease, or theobromin in persons suffering from Bright's disease with dechloruration. Such are the means more generally employed.

There are cases, however, where, in spite of the most intelligent medical treatment, the cedema, instead of diminishing, remains stationary or increases to the extent that anasarca invades the lower limbs, the scrotum, the abdominal walls, etc. The patient can no longer lie down, passes his nights in a chair, while dyspnea, due to the ædema which has probably invaded the peritoneum, the pleura, the pericardium, and intoxication of the bulb produced by the retention of the elements of the urine, is very marked.

In such cases it is necessary to evacuate the ædema by cutaneous drainage. There are thus two principal indications to drainage: irreducibility of the cedema and intolerance of the patient towards this cedema. The counter-indications are: œdema due to compression, which can always be rectified, and elephantiasis

from stasis of the lymph. Drainage can be effected by acupuncture, incision, or the trocar. For either of these operations the skin should be disinfected by washing with ether or alcohol, both sufficiently antiseptic and possessing further the advantage of removing all trace of grease. The drainage should be made, says Dr. Milian, behind the malleolus of the ankle for a patient keeping the sitting position, and on the inside of the thigh for the

borizontal position.

The instrument for making the puncture is the The wound should be a quarter of an inch is length, intersecting the whole thickness of the skin so as to attain the cellular tissue beneath. The liquid of the cedema trickles immediately from the incision. lacisions are made with the bistoury. Recommended by Furbinger, they are seldom employed to-day as they are painful and heal with difficulty. Three or four thes in length, they go right down to the aponeurosis and are drawn in the axis of the limb.

The liquid flows in more or less abundance and that continuously, as the distended and ill-nourished tegunents have no tendency to heal spontaneously. Unless recautions are taken, the liquid will traverse the near of the patient, the bed, and even the mattress. from of the patient, the bed, and even the mattress. Consequently the mattress should be protected by apermeable cloth, passed under the sheet, a thrice-filded sheet placed under the patient and changed they day, while irritation of the teguments should be strong around the wound of a slightly exented by a coating around the wound of a slightly intiseptic paste:

Resorcin, 15 gr. Oxide of zinc, 4 dr. Vaseline, 4 dr.

Lanoline, 4 dr.

The limb is afterwards enveloped in a thick layer of absorbent wool, which is changed as frequently as

necessary.

The inconvenience of these punctures or incisions lies precisely in this constant wetting, which exposes the patient to pulmonary complications, as bronchopneumonia, in spite of every protection. To guarantee against these possibilities, drainage by trocars is recommended. By this method the liquid is conducted directly from the cellular tissue to a receptacle, thus avoiding wetting the patient.

The models of trocars are various, but the principal are those of Southey and Curschmann. The latter has the advantage of being larger, and thus not so easily obstructed by a clot. A more simple method is that of an ordinary drainage rubber tube of 1 to 2 ft. in length, and passed underneath the skin in the form of a seton, leaving the ends hanging down, through which the liquid flows. The duration of the drainage

should not exceed 24 hours.

Among the complications may be mentioned slight delirium or obnubilation. Gumbrecht cites the case of a young girl who was very anæmic, and suffered from chronic nephritis, with general anasarca. Several trocars were placed in the legs, giving issue to 20 quarts of liquid in the two hours. The night following she died, and the immediate cause of death was believed to be anæmia of the brain. Again the little wound is frequently inclined to become fistulous and run continuously. But the most serious complication is infection (lymphangitis, erysipelas) from absence of cleanliness.

In spite of these possible disadvantages, mechanical drainage can give considerable relief where therapeutic

agents have failed.

### GERMANY.

Berlin, Jan. 373, 1909 Ar the Verein für Innere Medizin, Hr. Senator spoke

INFLUENCE OF THE BODY TEMPERATURE ON THE SUGAR CONSTITUENT OF THE BLOOD. He said that Lüthje, as well as his pupils and collaborators, found that in dogs, from which the pancreas had been removed, the sugar excretion, and in normal dogs the sugar of the blood increased with fall of the outer temperature, and diminished when the outside temperature rose. In the meantime these statements had been contradicted by several authors (Minkowski, Mohr). Even in phloridzin diabetes such an influence had not been established. One point had not been considered, and that was, the behaviour of the temperature in the various temperature-surroundings. In men and the so-called homothermous animals their temperatures remained normal during varied external temperatures in virtue of their heat regulating external temperatures in virtue of their near regulating functions, but only within certain limits, which, as the speaker had shown 40 years ago, in the case of fasting, unclothed, and non-moving individuals lay between 27 and 35° C., i.e., between these limits he could keep his body temperature nearly constant. Whether to allow wider limits, in the case of animals with varieties of averaged temperature of 30° and with variations of external temperature of 20° and over, was more than doubtful.

The influence of the body temperature in the formation and excretion of sugar had not yet been brought to a conclusion; statements regarding the excretion of sugar in diabetics when in a feverish condition were contradictory; according to recent statements there was an increase of excretion during rises of temperature. There was a similar contradiction in temperature. regard to alimentary glycosuria in fever. Thus in the human subject in infective diseases with high temperature there was said to be a strong tendency to alimentary glycosuria, whilst other authors disputed this. P. F. Richter never saw glycosuria during the hyperæmia of rabbits after Sachs-Aronsohn's brain puncture. Aronsohn saw adrenalin glycosuria disappear after similar puncture, others did not see it.

The statements regarding the sugar constituent of the blood in heightened temperatures were also at variance. The same applied to the supply of glycogen of the body.

In all these various investigations the fundamental question had practically not been discussed at all, how the raising of the body temperature itself acted on the sugar constituent of the blood. For this reason the speaker had himself taken the subject up. For the production of such temperatures there were two methods to hand: retention of the body heat by raising the outside temperature, and the "warm" puncture.

(1) As regards this we had only the experiments of Noel Paton, which gave a rather considerable increase of the sugar constituent. The speaker scarcely ever succeeded in keeping rabbits alive many hours with an uninterrupted high temperature. Only twice did animals remain alive 4 or 5 hours. They were fed several days beforehand, their temperatures taken once or twice a day, and their urine tested for albumin and sugar; 20 to 25 c.cm. of blood were then taken from one of the carotids, and the sugar constituent ascertained. Some days later, when no deviation from the normal was observed in the animal, the artificial warming was begun, and after some hours blood was taken from the other carotid. In both cases a distinct increase of the sugar constituent was determined, which must clearly be looked upon as a consequence of the raised temperature.

(2) Up to the present there were no investigations on this point. He himself had made ten experiments on nine animals, which, without exception, showed an increase of the sugar constituent after rise of temperature, and from 8 per cent. to 30 per cent. with an average of 17.2 per cent. In both series of experiments the urine was perfectly free from sugar, as the sugar constituent, although increased, was not high enough to cause glycosuria. In order to decide the question whether in the case of the "warm" puncture other elements play a part—irritation or paralysis of nerves he tried to prevent the rise of temperature by cooling. This experiment, however, failed, as the rabbits were very sensitive to it and quickly collapsed. Anti-thermic medicines could not be tried, as the carbohydrates of the system were especially influenced by them, glycogen turned into sugar, even glycosuria might be set un

on what did this increase of sugar depend? Two possibilities here came into consideration: (1) More glycogen might reach the blood from the glycogenforming organs (liver and muscles); (2) the cause of the rise might be decomposition of albumin; as was known sugar might be split off even from albumin.

As regarded the influence of the infective fever-high temperature on the sugar constituent of the blood, the raising of the temperature and of the fatty albumin increased it. Inversely the bacteria or the products of their tissue changes, causing the infective process, might lower it; the condition of the patient as regarded nutrition was further of influence. From this, according to the predominance of the various factors, the varying statements as regarded fever were to be explained.

The speaker then quoted the observation of v. Noorden, according to which, in a pneumonic patient with a large sugar constituent of the blood, no glycosuria took place, which v. Noorden attributed to an imperviousness to sugar of the kidney, dependent on the febrile affection.

# AUSTRIA.

Vienna, Jan. 3rd, 1909.

MENINGO-COCCI SERUM.

At the Gesellschaft, Kraus and Baecher gave proof of their new serum for meningitis, with which they have been experimenting for some time past, both in the Sero-Therapeutic Institute and the wards of the Children's Hospital. The first proof was by the opsonic method of Neufeld, which, as expected, was quite satisfactory. The next was the application, the most important of all. They prefer Pfeiffer's form of

injecting it into the peritoneum, where both anti-toxic and opsonic power can be accurately measured. The therapeutic results which they have obtained in hospital are that two-thirds of the hopeless cases have recovered. The cases selected were those given up as hopeless, so that mild conditions have not yet been tested.

ABSCESS IN TEMPORAL LOBE.

Ferdinand presented a young woman, æt 17, cq whom he had operated for abscess in the right temporal region of the brain. She had suffered for ten years from purulent discharges from the right ear and antrum, for which she came to hospital for radical cure. This operation was performed in the usual manner, and all went on well till the ninth day, when she suddenly took a fit and remained unconscious for some time. These epileptic fits repeated themselves till the fifteenth day after the operation, when she commenced to complain of severe pain in the right side of the head. It was then resolved to open up the cranium, as the temperature had risen to 38.4 Cent., or 105.12° F., and insensibility deepening, while the mouth was drawn to the left from pressure on the facial nerve, with stiffness in the neck and acute reflex, all indicating central disturbance, as the fundus was healthy.

The wound was re-opened, and the healthy granulating tissue removed with the whole tympanum and antrum, making an opening through the dura mater an inch wide. The dura mater, when reached, was healthy-looking, but vaulted or blown out. In the temporal lobe, about a centimetre below the dura mater, an abscess was found containing a tablespoonful of putrid, offensive-smelling pus. The whole was cleaned cut and dressed antiseptically, with the result that seven weeks after the operation she is perfectly well again.

HYDRO-URETERS AND PROSTATIC HYPERTROPHY. Tandler and Zuckerkandl gave an exhaustive anatomical and ætiological description of hydro-ureters, or, as they are sometimes described, plicæ uretericæ, or, in simple language, a bending and clipping of the ureters between the bladder and the kidney. We have always been taught that hypertrophy of the prostate leads to distension of the bladder and ureter from the undue retention of the urine. Tandler and Zuckerkandl have challenged this theory, and now maintain that the hypertrophy of the prostate acts in a directly anatomical fashion by raising the trigonum upwards behind and jamming the loose ureter against the vas deferens makes a sharp bend in the ureters that hold back the urine from passing on to the bladder, and thus causing distension of the ureter above the kink. From this reasoning the ureter is not affected by the retention of urine in the bladder, but from the increase of the middle lobe of the prostate distorting the position of the trigonum upwards and outwards till the uneter gets entangled and warped with the vas deferens. It is therefore not necessary to assume that the purulent discharge from the upper part is an ascending infection, as this is often present when the bladder is perfectly aseptic. It is more correct to assume a harmatogenous infection in these cases; therefore, infection is not always in consonance with the state of the bladder, or vice versa.

The correct therapy in severe cases of hypertrophy of the prostate would be to cut the vas deferens. This operation has been done recently in a more indirect way by castration, which has the effect of causing the vas deferens to wither and shrink, allowing more freedom for the functional action of the ureter.

Intermitting Ectasia of Stomach.

INTERMITTING ECTASIA OF STOMACH.

Zweig showed two men who, for a few weeks or months at a time, are troubled with insufficient action of the stomach, vomiting food taken the previous day with decided dilatation of the organ. All at once, as by magic, these adverse symptoms disappear, and the patient feels well and can enjoy any kind of food. The real cause seems to depend on a spastic condition of the pylorus, which has led to ectasia and hypertrophy of the gastric muscles. The cause may be nervous, or due to slight ulceration, or fissures in the pylorus. The therapy pointed to fluid diet, washing out of the organ with the oil cure.

Schwarz said that it often occurred that by want of

co-ordination the gastric muscles were thrown into

spasm when the pylorus was perfectly patent.
Escherich was of opinion that pyloric spasm was more frequent in the infant than the adult, which may be due in many cases to the improper constituents of the milk

Schmidt thought that stenosis in these cases had not been logically excluded, but Zweig replied that he found it difficult to exclude this suggestion, but the sudden and healthy intervals were very difficult to explain after such diagnosis.

# FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

SIR DONALD CURRIE'S OFFER TO THE NEW PERTH INFIRMARY.—The following correspondence in reference To Sir Donald Currie's offer has been published:—
"Dec. 22nd, 1908.—Dear Sir Donald,—The Lord
Provost submitted your letter of November 28th to
him to the directors, who, yielding to a strong expression of public opinion, exceedingly regret to inform you that they do not see their way to accepting the offer contained in your letter owing to the time limit imposed by you, and your condition as to the appointment of an architect. Notwithstanding this, I am desired to express the hope that you may see your way to give them a smaller contribution towards the cost of a new infirmary, which has now been resolved upon.—Yours faithfully, PAT. MARTIN, Secretary."—Dec. 28th, 1908.—Dear Sir,—I beg to acknowledge receipt of your letter of the 22nd inst., which has been forwarded to me from Perthshire, and I gather from what appears in the public Press that the friends of the Perth Infirmary see their way to provide the funds which are necessary for a new building without the help which I offered to the Lord Provost in response to an appeal he, with Mr. and Mrs. Murray, of Taymount, made to me at Garth. In my letter to Lord I was prepared to help.—Yours truly, DONALD CURRIE." Provost Cuthbert I stated explicitly the terms on which

EDISBURGH ROYAL INFIRMARY—MEMORIAL TO THE 1 ATE MISS SPENCER.—There was unveiled on the last day of the year, in the chapel of the Infirmary, a mural tablet to the memory of the late Miss Frances Elizabeth Spencer, who for so many years was superintendent of nurses in the institution. After a short service by the chaplain, Mrs. George Kerr, on behalf of the managers, unveiled the tablet, which consists of a brass plate with a wrought inscription bearing that the tablet was erected on the unanimous resolution of the managers in grateful recognition of Miss Spencer's devoted and valuable services. The inscription is encircled by a wreath of oak leaves and acorns,

and the brass is set on a slab of statuary marble.

Annual Report.—The annual report, which is to be submitted to the statutory meeting of the contributors on Monday, January 4th, has just been issued. Apart from the usual statistical matter, it contains little of general interest. During the year 11,754 in-patients were treated: cured, 6,285; relieved, 3,444; discharged for other reasons, 380; died, 823; remaining under treatment, 822. Of the cases terminating as above, 4,104 were medical, 6,828 surgical. In comparison 4,104 were medical, 6,828 surgical. In comparison with last year, the numbers show an increase of 614; the average daily number of patients was 836, against 832; of children, 76, against 82; the average duration of treatment was 26.4 days, as against 27.3 days. Of cases admitted, Edinburgh furnished 5,823; Leith, 436; the country, 4,716. The death-rate was 7 per cent., as against 7.31; deducting 154 deaths within 48 hours of admission, it was 5.76 per cent., or 0.7 per cent. more than last year. The number of out-patients was more than last year. The number of out-patients was \$6,892. The ordinary income was £35,304, a decrease of £402, and the ordinary expenditure was £34.955, an increase of £1,476, due largely to enhanced cost of many articles in use. The entire ordinary expenditure (including out-patient department) per occupied bed was £65 148. 8\frac{1}{4}d., or an increase of £1 98. 2d. over 1907. New Works.—During the year the drainage and structural alterations, and the hot-water installation

and renewal of electrical fittings have been completed in the central surgical block. This completes the great scheme of re-drainage started eight years ago. Sundry improvements to obviate risks from fire have been introduced, and a number of other minor alterations have been made. The new medical out-patient department has been commenced, and will, it is hoped, be completed by the end of February. The principal changes on the staff have been the resignation of Dr. Murdoch Brown on account of the state of his health, and the translation of Mr. Caird from the ordinary surgical staff to the office of Professor of Clinical Surgery, upon the important duties of which he enters "sustained by the esteem and followed by the best wishes of all who have hitherto been associated with him in his work."

# BELFAST

PUBLIC HEALTH.—If the statistics given at the meeting of the City Council on New Year's Day are to be relied upon, Belfast is to be congratulated on a very marked improvement in the public health. For the last four weeks of the year the total deathrate from all causes was 17.7, and from zymotic diseases 0.4, as compared with 25.8 from all causes, and 3.0 from zymotic diseases in the same period last year. The death-rate for the year showed a reduction in every department except that of infant mortality when compared with that of the previous year, and the infant mortality only showed a fractional increase; probably owing to the severe weather in the beginning of the year. Even this, however, is rather disappointing, as after the active work of the Infant Mortality section of the Irish Women's Health Association one would have hoped for a marked decrease. The total death-rate for the year, calculated on the Irish Registrar-General's basis, was 19.3, while calculated on the English and Scotch bases, it should only be 17.5. In any case, it is a marked improvement on former years, and evidently the expenditure on the Health Commission, high as it was, was well-spent money. During the last month of the year there were four cases of cerebro-spinal meningitis notified, showing that the disease is not yet extinct.

THE UNIVERSITY COMMISSION.—The Commissioners who are entrusted with the task of drawing up the statutes and regulations of the new Queen's University statutes and regulations of the new Queen's University of Belfast have been meeting daily since the 29th ult. They are His Honour Judge Shaw, K.C., Chairman; Rev. Thos. Hamilton, Vice-Chancellor; Professor Dill, Sir Donald MacAlister, Mr. R. T. Martin, Sir Arthur Rucker, and Professor Symington. Meetings of the professors in the various faculties have drawn out a will able of study and examinations for each faculty. syllabus of study and examinations for each faculty, and these are being considered by the Commission. It is understood that the plans of the Royal University will be departed from in several important respects as regards the medical curriculum, at any rate. The views of the Commissioners are not known, of course, but the general opinion is that the preliminary year of Arts study will be dropped, allowing the student, after a searching matriculation examination, to enter at once on his professional studies. The Senate of the University has also met, and has appointed a building committee to inquire at once into the question of the new buildings that will be needed.

# LIVERPOOL.

MUSCARINE AND NEURITIS.—A peculiar case came before the Liverpool Coroner on December 23rd when inquiring into the cause of a Mr. Gilman's death neuritis or muscarine.

The facts briefly are:—Gilman, æt. 33, a "ship-owner's manager," was going on his holiday to Wales, and, being troubled with gnats, took with him, on the advice of a friend, a liniment from a homoeopathic establishment containing muscarine to counteract or allay the irritation of gnat bites.

His wife told the jury he used it "for several nights on his arms and legs." But why on the legs for gnat bites? "When they returned home on September

26th," she further tells us, "he lapsed into his former state of health." From this one would infer that deceased was in a bad state of health before they went on their holiday; but what he was suffering from at that time we have no further knowledge.

On his return home the medical testimony commences with multiple neuritis, which all agree to be present, but the proximate cause is a puzzle, as the deceased was a very abstemious man and never exposed to any of the probable causes usually associated with this disease! Was it this liniment that was used for gnat bites or some other poison? This lotion, according to the biological chemist, contained alcohol and soap with "a small amount of 'muscarine' found in certain fungi, by both chemical and physiological tests, which has the property of stopping the heart in a relaxed condition, and causing paralysis of the nervous system." At the post-mortem, "the body was well nourished, healthy, and muscular." "All the organs were healthy, with considerable congestion of both lungs, heart and intestines." "He had all the symptoms of having died from failure of heart and respiration."

Now here is a puzzle to place before a coroner and a jury by three wiseacres of the profession! All seem to agree in peripheral neuritis, but none took the trouble to confirm it. One ventures on muscarine poisoning from the lotion, affirming that it acted more potently when applied to the cutaneous surface than when taken internally. Would such a small quantity produce peripheral neuritis? And, furthermore, could the poison remain in the body from September 26th to December 10th—nearly three months—and finally kill by cardiac diastole? It was suggested that he must have used it later than September 26th, but one cannot see any reason for doing this, as no gnats were likely to trouble him about the Mersey

The cryptic evidence of the wife that "he lapsed into his former state of (bad) health" reveals more to us than the toxic action of agaricus muscaris, which is far too remote and fanciful to be scientific or worthy of respect. It appears the deceased was in a low state of health before he went on his holiday, but from what cause or what his former health was we have no means of determining from the evidence. It is surely a misfortune to see the profession propounding such vague theories with so little to support them, which cannot raise our esteem in the mind of the layman or our real worth in a court of law. Such cases are more fruitful of ridicule than reason, and should be discouraged.

# LETTERS TO THE EDITOR.

# RHEUMATOID ARTHRITIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,-Dr. William Murrell's clinical lecture in your issue of this week presents an admirable epitome of the ætiology, pathology, and treatment of rheumatoid arthritis, certainly the best brief statement that I for a long time have encountered. He would add much to the value of his contribution to our knowledge of the therapeutics of chronic phases of the disease if he could follow it with an examination of the values of the various natural hot springs to which so many patients now resort. After observation on the spot at several foreign spas, frequent visits to Aix-les-Bains, and one prolonged stay at Schinznach, I remain very sceptical as to the actual effects of the waters, either as regards their external powers through bathing, or as internal medicines. There is talk about "radioactivity" in these natural hot springs, but is there any scientific evidence of its existence? What I have noticed at these places is temporary abatement of symptoms, due to the warmth of the climate. Aix-les-Bains, for example, in summer is one of the hottest places in Europe; and patients who spend many hours every day basking in the sun in a well-sheltered hotel garden, do undoubtedly gain great relief from pain and discomfort; and this is especially noticeable in those coming from cold and damp climates. If such patients could instead be sent to Egypt or, perhaps preferably, to Algiers, for a winter, would not the ultimate permanent result be better? Dr. Murrell could, no doubt, give a valuable opinion on this point. I have a case now under observation—a lady of middle-age, with slight general chronic arthritis—who is taking iodide of potassium and guaiacol simultaneously, and shows improvement under the treatment. She is living in a southern county on a hillside 300 ft. above the sea, with full south exposure. The subsoil is heavy clay, but this I hold to be no disadvantage at such a height and with resulting good natural drainage. I believe a lower-lying gravel or sand subsoil often determines a more unfavourable local climate than clay on a hill. Perhaps Dr. Murrell could tell us something on this last point.

I am, Sir, yours truly,

A STUDENT OF SIXTY.

Dec. 29th, 1908.

THE NEWSPAPER PRESS AND QUACKERY.

To the Editor of The Medical Press and Circular.

SIR,-Can nothing be done to bring home to the Press the real character of the traffic they are abetting by insertion of the quack advertisements which now occupy so large a space in the majority of newspapers. Up to recent years it has been possible to single out a considerable proportion of newspapers which not only excluded the lowest classes of quack puffs, but also took every occasion to expose fraudulent medical methods of every kind. The number of such papers is rapidly diminishing. Many papers which stand in the very front rank of journalism contain numbers of advertisements which to the eye of the editors, or at least of regular medical contributors to their editorial columns, display the word fraud, so to say, written in big letters across their faces. To-day in a leading London paper I see an enormous and costly puff of a medicine which has been several times denounced as a vile swindle in the High Courts of Justice. regard to some papers to which the proprietors are now admitting advertisements that formerly they would have rejected with scorn, it is evident that the managers are not aware of what the editors are writing, and the editors not aware of what the managers are doing. I enclose a leading article and some advertisements from a paper of the first rank. The article denounces a system of quackery exposed in the Law Courts, and laments the fact that mis-leading advertisements should find admission to respectable papers. The advertisements of this same quackery, which I send with their dates appended, are from this very paper, and, as you will see, these were appearing before and have gone on appearing regularly since the trial. Exactly the same thing occurred in the same paper lately in the matter of a cruel City swindle. This was exposed and denounced editorially in the paper whilst all along it had been advertised in the form of puffs printed next to reading matter in the same journal. Another great paper having lately given place to a series of able and exhaustive articles on "Infantile Mortality," in which the pernicious effects of "baby quieting" medicines were fully discussed, allowed immediately afterwards a long series of puffs of one of these nostrums to appear with a heading in which its value in preventing infantile mortality was set forth. One wonders whether the irony of these transactions may have been completed by the fatal drugging of one of the offspring of the noble owner of the great journal in question. What more likely than that the head nurse in charge of the babies of the house should have relied upon a poisonous narcotic under the belief that it must be "the best thing" since it was advertised in lordship's "paper.

I am, Sir, yours truly,
HENRY SEWILL.

Dec. 29th, 1908.

A WARNING FROM THE MEDICAL DEFENCE UNION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—May I ask, through your columns, medical practitioners who may be applied to for pecuniary or other assistance by a person calling himself "Dr. J. Backus Taylor, M.R.C.S., L.R.C.P.," not to grant any such aid without first communicating with me? Medical agents should also guard themselves in a similar manner before placing the name of this person upon their lists for employment as assistant or locum tentns, and sending them to clients. There is a Dr. Backus Taylor upon the Medical Register, but, from circumstances which have come to my knowledge, it would be as well not to assume that the individual of whom I write is the qualified practitioner of that name in the Register.

I shall be glad to afford any information to anyone applying to me either personally or by letter.

I am, Sir, yours truly,

A. G. BATEMAN,
General Secretary.

4 Trafalgar Square, London, W.C.

AN AFFLICTION HE CANNOT MAKE LIGHT OF-LAMPLIGHTER'S ARM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. Sir,—If the complaint known by the name of lamplighter's arm is caused "by the constant trickling of rain from the pole into his sleeve," what could be easier than have a collar of tin or wood near the hand projecting far enough to protect the sleeve of the lamplighter, something like the flange seen in old pictures of the lace used in tilting to protect the user's hand. Hammer toe, housemaids' knee, tennis elbow, and now lamplighter's arm!

I am, Sir, yours truly,
A. D.

London, W.

# **OBITUARY.**

CHARLES KNOTT, M.R.C.S., M.R.C.P.ED.

We regret to record the death of Dr. Charles
Knott, who for twenty years held the post of
Medical Superintendent to Portsmouth Workhouse
at Southsea. Dr. Knott studied at Guy's Hospital and became qualified as a member of
the Royal College of Surgeons of England in 1872,
and as a member of the Royal College of Physicians
of Edinburgh in 1881. At Portsmouth, for upwards
of 30 years, Dr. Knott held many appointments, chief
among which the following may be noted:—President of the south branch of the British Medical Association, Chairman and Lecturer to the St. John
Ambulance Association and Chief Surgeon to the
Ambulance Brigade, Surgeon-Colonel to the 3rd
Volunteer Battalion (Hants Regiment), Honorary
Surgeon to the Portsmouth Swimming Club, and
Medical Officer of Health for Landport. Dr. Knott
was a Knight of Grace of the Order of St. John of
Jerusalem in England.

# REVIEWS OF BOOKS.

A SHORT PRACTICE OF MIDWIFERY FOR NURSES. (a)

When a book reaches its third edition it is generally very well known, and this fact is sufficient proof of the value of the work, and shows the appreciation with which it has been received amongst that part of the public or profession for which the book was originally compiled. Dr. Jellett has brought the present edition of his book fully up-to-date, particularly

in those parts which deal with the practice of midwifery that have undergone the greatest changes, and to which a large amount of attention has been paid in recent years—the prophylactic treatment of sepsis. As the author says in his opening chapter, "It is no exaggeration to say that the most essential knowledge in midwifery is the knowledge of the meaning and the practice of asepsis." The author describes the methods carried out in the Rotunda Hospital for obtaining this end, and points out the advantages to be derived from the use of rubber gloves, and the necessity for adopting their use is impressed; this is one of the most recent improvements in the technique for obtaining asepsis, and its adoption is to be greatly desired.

The author points out all through his book those cases in which medical aid is to be sent for in accordance with the rules of the Central Midwives Board, and he explains the operative measures which may have to be adopted, not for the nurse to carry them out herself, but so that she may be an efficient assistant to the medical man in the treatment of the patient.

The teaching in Dr. Jellett's book is thoroughly sound, and both simply and clearly expressed. There are few points which may be objected to, and most are matters on which different opinions are held.

The definition given of the first stage of labour is misleading. The full dilatation of the os is the end of the first stage, and although the membranes usually rupture at this time, that phenomenon is not part of the end of the first stage. The definition given tends to promote a very erroneous idea which is commonly held, that because the membranes have ruptured the woman must be in the second stage.

In the management of the first stage the author recommends to allow or induce the patient to walk about. The tendency amongst nurses is often to persist in this, and so to tire out the patient instead of allowing the woman to follow her own instincts.

A short note on cancer of the uterus is added, with the object of enabling nurses to advise women to seek medical advice when they have symptoms which may be due to, say, cancer, and so place themselves in a position to have the condition diagnosed at a time when the disease is still within the scope of surgery and offers a reasonable hope of permanent cure. If nurses will read this note and follow the advice given, the large number of deplorable cases of inoperable cancer which are at present seen will be greatly reduced. The advice in this note is chiefly directed to the removal of some of the most erroneous and widespread popular beliefs about cancer, and the natural course which the onset of the menopause should take in women.

In the appendix are added the Regulations of the Central Midwives Board, and a useful glossary of medical terms.

The third edition of Dr. Jellett's book is a most useful publication, and one which will repay every nurse who obtains it and studies the teaching and advice embodied in it.

THE DUBLIN UNIVERSITY CALENDAR. (a) THE Dublin University Calendar for 1908-9 is presented in the same form as its predecessors of the past few years. It is doubtless a matter of convenience to the student to have in one volume the College regulations and the ordinary examination papers, but graduates of a decade back will regret the banishment to less accessible regions of the lists of graduates who in the past had won distinctions of one kind or another. We look in vain in the present volume for any sign of the great reforms which everyone who knows Trinity College knows to be necessary, if she is to retain her position in the face of the competition that will soon threaten her. The truth is we can hardly expect that the Board, in whose hands is all the power, will either originate or consent to an adequate scheme of reform. To come from great matters to small, we are glad to note that the

<sup>(</sup>a) "A Short Practice of Midwifery for Nurses, as used in the Edunda Hospital, Dublin, for the past ten years." By Henry Jellett, E.A. M.D., F.R.C.P.I., Past Assistant Master Rotunda Hospital, Paird Edition. 453 pages, six plates, and 164 illustrations. London:

<sup>(</sup>a) "The Dublin University Calendar for the year 1908-1909, to which are added the Ordinary Papers set in 1907-1908." Vol. I. Pp. 463. Dublin: Hodges, Figgis & Co. 1908.

College authorities have decided to make it compulsory on junior students attending lectures to live either in College or in residences approved by a committee appointed for the purpose. The sections of the Calendar dealing with the School of Physic contain some inaccuracies, particularly in the lists of the staff of the school and of Sir Patrick Dun's Hospital. We would suggest to those in charge of the Post-Graduate Course that it could be made more attractive by occasional variations in the list of subjects treated. Thus we think that an occasional course in Anæsthetics" would be of interest to the practitioners who constitute the class, while some of the specialities at present in the list might be dropped for a time, and others substituted.

NATURAL THERAPY. (a)
This book is a practical and useful summary of the various kinds of treatment which are conveniently grouped under the heading of "Natural Therapy." We know of no work that covers the same ground, and on that account it makes a convenient manual of reference for the general practitioner or the consultant. In these days of extended and multifarious knowledge, such a companion is absolutely necessary in order to keep abreast of medical progress. The author has divided his subject into six sections as regards the treatment of disease—namely:—(1) The Use of Water. (2) Heat and Light. (3) Massage. (4) Electricity. (5) Diet, and (6) The Modern "Cure." These various sections are then discussed systematically and scientifically, beginning with an interesting historical summary, and proceeding to general principles, the physiological effect on the different systems, and so on. The whole thing is practical, thorough, and scientific. We notice that in thermotherapy, under "dry heat," the author makes a short mention of the Tallerman treatment, introduced in 1893. As a matter of fact, it was introduced considerably before that date, and gave rise to other forms of apparatus, including the "radiant luminous heat." The latter method, introduced, according to the author, by Dowsing in 1896, is held to have "considerable advantages over all other systems." We find nothing adduced to support that statement, and from a close acquaintance with the results of the Tallerman apparatus, we feel convinced that these cannot be surpassed in curable cases. At any rate, the burden of proof lies with those who, while seizing upon the principle of Tallerman's dry heat, add to it light and chemical rays, for which they claim the therapeutic wirtue. Surely the logical plan would be to try the effect of light and chemical rays alone, and compare them with dry heat alone. The X-rays and Finsen light are dismissed shortly. A useful account is given of the rest cure, about which every medical man should be fully informed. Speaking generally, the book will repay careful perusal by all who wish to learn the practical aspects of various physical treatments which nowadays loom so largely on the medica! horizon. The special experience of the author has enabled him to produce a first-rate book. There are 30 plates and 25 illustrations, and the volume is issued in Messrs. Wright's well-known excellency of publication.

THE PROLONGATION OF LIFE. (b) This volume forms the third and enlarged edition of the author's lecture delivered before the Royal College of Physicians on December 3rd, 1903. The keynote to the author's teaching is found in the motto which is inscribed on the title-page, "Work and moderation are the main sources of health, happiness and long life." He maintains that by careful arrangement of the mode of life we may live to go or even 100 years. Even when hereditary tendencies seem to weigh against a person's chances of living long, these tendencies may be altogether overcome by a careful adjustment and regulation of one's habits, food,

dress, and daily exercise. In this edition a short description of the more common articles of food has been added, together with some account of their rôle

in the nutrition of the body.

The author is strongly in favour of regular daily exercise. Walking is the most natural form of exercise. The advantages of walking are numerous, and some of these, as described by the author, we have never seen stated in print before. He has known many persons of advanced life greatly benefited by a daily walk, and remarks that they should always be encouraged to take this, even if they have but re-cently recovered from an illness. Great moderation in flesh food is declared to be necessary if we would live long and healthy lives. Excessive smoking is referred to as a possible cause of arterio-sclerosis, and this, together with the drinking of strong tea in large

quantities, must be condemned.

The book is written in a most interesting and attractive style. It makes one wish to carry out the author's advice in spite of oneself. There is nothing "faddy" "faddy" in any of the statements made by the author. His teaching is dictated by strong commonsense which at once appeals to the reader. The art of living long is by no means easy to follow, but if there is a royal road to its acquirement it will be found to lead along the route so carefully mapped out by the author of this interesting guide. There can be no doubt that many useful lives are prematurely lost to society for lack of due care as to their personal preservation. A study of Sir H. Weber's book will go a long way towards teaching physicians how they must instruct their patients as to the means to be adopted in order to attain to an age beyond the threescore-years-and-ten. The book forms delightful reading, and we consider that its precepts are invaluable to every medical practitioner.

# LITERARY NOTES.

THE third edition of Rawling's "Landmarks and Surface Markings of the Human Body" (H. K. Lewis, 5s. net.) remains of manageable dimensions, the author having resisted the temptation to add anything beyond new illustrations. The illustrations, thirtyone in number, are of special excellence, and justify the popularity that the work has attained. It is a work, indeed, which no practitioner can afford to be without, the need for such a guide making itself felt at each instant in daily practice. It is admirably printed and does credit to the publisher.

THE comely volume of "Memoirs of Dr. Edmund Symes-Thompson," from the pen of his wife, recalls to us an urbane gentleman and accomplished physician, whose death a few months since was sincerely regretted in London medical circles. The late Dr. Symes-Thompson was a man of prodigious and varied activity, whose labours comprised many objects only distantly related to medicine. Profoundly, but not ostentatiously religious, he was an enthusiastic member of the Guild of St. Luke, and organised the annual service at St. Paul's Cathedral, which has since become so popular a festival. He was one of the founders of the Brompton Hospital for Consumption, and was for years the Gresham Lecturer in Medicine. Well may his memory be cherished by those to whom he had endeared himself by a life of consistent kindness and well-doing.

DR. L. F. BARKER'S "Anatomical Terminology" (Churchill, 5s. net) is based on the Basle Anatomical Nomenclature (B.N.A.), which comprises a list of some 4,500 anatomical terms accepted as the most suitable designations for the various parts of the human anatomy visible to the naked eye. One name only is given to each structure, so that the cumber-some mass of synonyms can be swept away. Considering that the total number of terms, including synonyms, exceeds 30,000, it is no small achieve-

<sup>(</sup>a) "Manual of Natural Therapy." By Thomas D. Luke, M.D., F.R.C.8.Edin., formerly Physician at Smedley's Hospital, Matlock, &c., &c. Bristol: John Wright and Sons. 1908. Price 7s. 6d. net. (b) "On Means for the Prolongation of Life." By Sir Hermann Weber, M.D., F.R.C.P., Consulting Physicianto the German Hospital, the National Hospital for Co-sumption, Ventnor, &c., &c. London: John Bale, Sonsand Danielason, Ltd. 1908 Price 4s. £d. net.

ment to have reduced the necessary number of terms to less than 5,000. Most of the terms are those in general use, but some have been selected from anatomical monographs, and a few have been introduced ad hoc. It constitutes a step in advance on the road to anatomical uniformity, though we still have to contend with the use of the vernacular equivalents for the Latin terms in foreign schools. It is to be hoped that authors, at any rate, will, in future, take this list as their guide, thereby earning the gratitude of their readers.

The growing importance of school hygiene is self-evident in these days. The younger members of the profession are finding School Medical Officerships a new field for their energies and ambitions. To such we cordially recommend "School Hygiene," by Robert A Lyster, M.D., Ch.B., B.Sc.Lond., D.P.H., B.Sc. Pub. Health (London: W. B. Clive). It is a handy little guide, and contains everything a school medical officer should know. Of special interest is the new chapter on the Medical Examination of Schools, which has been added in this second edition. The mode of carrying out the instructions laid down by the Education Act, which came into force in the beginning of the past year, is very fully explained. The author is evidently an expert on such matters. The book is well illustrated, and forms an excellent manual in every respect. Although the literature of school hygiene is destined to increase very rapidly in the near future, this small work will be able to hold its own against newcomers, provided the author keeps it within its present limits.

The valuable nature of the Reports of the London Ophthalmic Hospital, edited by Mr. W. Lang, F.R.C.S., is maintained in the present issue. Mr. Nettleship concludes his paper on "Retinitis Pigmentosa and Allied Diseases," which must have been a work of very great labour, considering the material dealt with and the number of generations which were followed out to establish points of heredity. It no doubt will rank as the most masterful contribution on the subject. W. T. Hancock's article on certain points in regard to the "Fields and Fundus Changes in Obstruction of the Central Artery of the Retina" is very interesting. The points he brings forward for attention are (1) The preservation of areas in the temporal field of vision after complete obstruction of the central artery. He has collected notes of 24 cases, besides the two met with in his own practice. As an explanation of the condition, he suggests that the peripheral retina derives nutrition from the choriocapillaris, and that the nasal portion is more functionally active than any other part of the retina. Mr. G. Coots, Curator, contributes a long paper on "Forms of Retinal Disease with Massive Exudation," with several micro-photographic plates, which ought to be read by all ophthalmologists.

### MEDICAL NEWS IN BRIEF.

### Disputed Insanity.

ERNEST GIRARD, a man of education, possessing some imaginary grievance against the British Government, was lately brought up in the South-West London Police Court, on a warrant, charged with assaulting Edward Evans, one of the common-keepers at Putney Heath.

The prisoner, a Swiss, has, in common with members of his family, made himself notorious by a remarkable habit of making Streatham Common his habitation, sieeping out on the common in all weathers. For years he indulged in this practice, using old newspapers as bedding. The family invariably left their litter behind them, and always resented the interference of the common-keepers, on whom fell the responsibility of clearing away the rubbish. They migrated from Streatham to Putney Heath, when the alleged assault took place. A difficulty has arisen, for while Dr. Scott, medical officer

of Brixton Gaol, reported the prisoner as insane, the authorities at Wandsworth Workhouse, to which place the man was sent by order of the Court to be dealt with as a person of unsound mind, dismissed him after detaining him but a few hours. Having in this way secured his liberty, a warrant was granted for his arrest.

Mr. de Grey (the magistrate) expressed his surprise at the action of the workhouse authorities.

Mr. Hanne (for the prosecution): They seem to be of a different opinion from Dr. Scott.

Mr. de Grey said Dr. Scott did not give certificates of insanity readily; he erred on the other side, as a rule. It is difficult to know what to do with the accused.

By direction of the magistrate, Dr. Felix Kempster, the police-surgeon, attended and examined the prisoner, confirming the opinion of Dr. Scott.

Mr. de Grey: You say he ought to be detained in a lunatic asylum?—Yes. He laboured under the hallucination that he is being watched by Government spies.

Mr. de Grey gave directions for the prisoner to be removed to an asylum.

#### Fatal Anæsthesia.

On Saturday last Dr. Danford Thomas held an inquiry concerning the death, in the Central London Throat and Ear Hospital, of a patient aged 23, a carpenter by trade, who had been admitted into the hospital the previous Thursday for the purpose of undergoing a surgical operation for the removal of excrescences at the back of the throat and nose. After the administration of ethyl chloride, the operation was successfully performed, when the patient showed signs of faintness, and expired within ten minutes, although every possible effort was made to restore him. His death was due to syncope whilst he was under the influence of the anæsthetic. Ethyl chloride had not, it was stated, previously proved fatal in any case at the hospital. The jury found that the anæsthetic was duly and properly administered, and that death was the result of misadventure.

An inquest was held at Preston, on the 23rd ult., on Dr. F. T. Walmsley, a councillor of the borough, who was found early that morning lying dead on the floor of his consulting-room, Moss Cottage, Fylde Road. Evidence was given showing that he had had heart trouble, and had been in the habit of taking chloral bromide to induce sleep.

A verdict was returned to the effect that death was due to heart failure, accelerated by an excessive dose of bromide taken by misadventure.

#### Death under an Operation at Burtor.

Death of a Medical Man at Preston.

AT Burton-on-Trent, last week, an inquest was held on the body of an infirmary patient named Samuel Sanders (51), who died while under the influence of chloroform.

The evidence showed that the deceased was suffering from an advanced cancerous growth in the mouth, and that the only hope of preventing an almost immediately fatal issue was an operation. Chloroform was administered by Dr. Ussher, the libuse surgeon, in the presence of two other medical practitioners. The patient suddenly collapsed, and all efforts to restore him proved futile. It was shown that the anæsthetic was carefully and skilfully administered, and that a post-mortem examination revealed an enlarged and diseased heart.

The jury returned a verdict of death from syncope, and expressed the view that the administration of chloroform was properly carried out.

Dr. WM. PORTER, Medical Officer of Portrush, has been presented with a motor bicycle by the inhabitants of the town on the occasion of his marriage, and as a token of their appreciation of his work and of the esteem in which they hold him.

For the purpose of making a presentation to Dr. Fred Wilson, the Medical Officer of Health at Newtown, a meeting of the Urban District Council was specially held on December 23rd.

### NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENCE requiring a reply in this column are particularly requested to make use of a Distinctive Signature or Initial, and to avoid the practice of signing themselves "Reader," "Subsoriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

BUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS.

ADVERTILEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.;
Quarter Page, £1 5s.; One-eighth, 13s. 6d.

The following reductions are made for a series:—Whole Page, 13
Insertions, at £3 10s.; 26 at £3 3s.; 55 insertions at £3, and
pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies,
Books, &c.:—Seven lines or under (70 words), &s. 6d. per
insertion; 6d. per line beyond.

ONTRIBUTORS are kindly requested to send their communica-tions, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

M.R.C.S., L.R.C.P.Lond.—A usual fee under the circumstances would be three guineas, having regard to the position of the

patient.

B. Samuels.—The book is out of print, but a second-hand copy might be obtained from a bookseller who deals in second-hand medical works.

DB. MAJENOIE (Paris).—No such preparation is referred to in the British Pharmacopeia (last edition), and we regret that, on inquiry, we are unable to give our correspondent the information he seeks.

### THE MODERN OVER-CULTURE OF CHILDREN.

THE MODERN OVER-CULTURE OF CHILDREN.

A TIMELY article in the January number of the Girl's Own Paper and Woman's Mayasins denounces, in no uncertain manner, the tendency of the modern mother to over-educate and over-develop young children at the age when the brain cannot stand the strain. With regard to the growing acquaintance of the child with his environment, it is a rafe rule to abstain from incessantly volunteering information. It is, says the writer, a terrible mistake to do as we have seen specially conscientious mothers do—constantly stimulate a little brain by offering jucid explanations, and everlastingly jointing out this, that, and the other, "taking pains" with him to an extent which would be heroically unselfash if it were not so utterly deluded and unnecessary. Is he playing at home? she must be at his elbow with suggestions—helping, guiding, prompting arranging—every moment. All this tugging at a growing brain is injurious." It is far kinder to keep a watchful oye on the child, leaving him to his own devices for amusement.

Vaccunst.—There is nothing specific in the "Leicester Method";

VACCINIST.—There is nothing specific in the "Leicoster Method"; indeed, we do not think that it was ever claimed to be. The method consists in an attempt to control small-pox outbreaks by disinfection, isolation, and the vaccination of contacts, without relying on universal compulsory vaccination. The experiment is a pretty one, and should be watched with interest. It is not often that a community will consent to sacrifice itself pro bono publico. This Leicoster, consciously or unconsciously, is doing, and their experience, so far, has not disappointed adherents to their dectrine. their doctrine.

STAMMER.—It is not necessary to send the child to a special school or teacher, if the mother is intelligent, sympathetic, and persevering. The great things are to regulate the breathing and to inspire confidence. Long breaths should be taken and consciously controlled, while the words, or rather syllables, are deliberately and slowly pronounced in a definite, organised manner. Keenness in the teacher also acts in inspiring confidence in the child.

DISTRAIN.—We cannot waste much sympathy on the gentleman ourselves. He clearly understood the position and declined to take any reasonable precaution. The case is a sad one, but hardly, we think, deserving of a special appeal, especially as he is not a medical man.

SCHOOL-BOY "HOWLERS."

SCHOOL-BOY "HOWLERS."

Our contemporary, the University Correspondent, has published some amusing "howlers" by schoolboys, of which we give a selection below:—

"Lumbago is a mineral for making lead-pencils."

"A the mometter is a short glass tube which regulates the weather."

weather.' The chief lakes of England are Ullswater, Derwentwater,

"John Bright is famous for an incurable disease."
"Ueen Elizabeth's face was thin and pale, but she was a stout Protestant."

"If care is not taken with dusty corners, microscopes will breed there."
"Things which are equal to other things are equal to one

mounter.
"Chivalry is when you feel cold."

HEYS SAW.—We should advise you not to go in for appointment. The minimum salary that should be offered

£250 a year (and that is little enough), together with all out-of-pocket expenses. Any man taking less is acting as a cut-throat in the competition, and makes it more difficult for his fellows

to obtain a fair wage. £150 a year is preposterous.

CHARTER.—The subject is hardly one for discussion in our columns. You should form your own views on it after reading the abundant literature on the matter. We agree. Chartered companies have a knack of being taken overby the Government.

### Meetings of the Societies, Tectures, &c.

TRUBBDAT, JANUARY 7TH.

RONTOEN SOCIETY (20, Hanover Square, W).—8.15 p.m.: Mr. C. E. S. Phillips: A Description of Three Sub-standards of Radio-activity recently prepared for the Rontgen Society (these Specimens will be exhibited). Mr. H. C. Head: A new Localising Apparatus designed by Staff-Surgeon Dr. Gillett.

NORTH-EAST LONDON CLINICAL SOCIETY (Prince of Wales's Hospital, Tottenham, N.—4.15 p.m.: Dr. De H. Hall: Hemorrhage from the Stomach, its Cause and Treatment.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SEIN (Leicester Square, W.C.).—6 p.m.: Othersfield Lecture: Bullous and Vesicular Eruptions: I., Urticara; II., Pemphigus, III. Pompholyx; IV., Varicella.

FRIDAY. JANUARY Sew

IV., Varicella.

FRIDAY, JANUARY STH.

BOYAL SOCIETY OF MEDICINE (LAETHOOLOGICAL SECTION) (20, Hanover Square, W).—5 p.m.: Discussion: A Discussion will be held "On the Modern Treatment of Syphilis, especially in regard to the Upper Respiratory Passages." The Discussion will be opened by Dr. Lieven, of Aix-la-Chapelle. Fellows and Members who wish to take part in the Discussion are requested to send their names as soon as possible to Dr. Cathcart, 35, Harley-Street, W.

ROYAL SOURCE OF MEMORIPA (C. M.)

Street, W. ROYAL SOCIETY OF MEDICINE (CLINICAL SECTION) (20, Hanover Square, W.).—8.30 p.m.: Dr. James Mackenzie: Demonstration of the Methods for Taking and Interpreting Graphic Records of the Movements of the Circulation. Dr. J. Mackenzie and Dr. T. Lewis will also take Tracings from Two Patients.

### Appointments.

CROOM, D. H., M.B., B.S.Edin., Certifying Surgeon under the Factory and Workshop Act for the Edinburgh District of the county of Edinburgh.

DAYIE, J. A., M.B., M.S.Aberd., Certifying Surgeon under the Factory and Workshop Act for the Forgue District of the county of Aberdeen.

MAY, OTTO, M.B., B.C.Cantab., M.R.C.P.Lond., Medical Registrar to Middlesex Hospital.

OLIVER, W. GRANT, L.D.S.Eng., Dental Surgeon to the Royal, Naval Hospital, Plymouth.

PATTERSON, NORMAN, M.B., B.Ch.Edin., F.R.C.S.Eng., Assistant Surgeon to the Golden Square Hospital for Diseases of the Throat.

Throat.

REARDON, J. C. P., L.B.C.P. and S.Edin., L.F.P.S.Glasg., Certifying Surgeon under the Factory and Workshop Act for the Kinghorn District of the county of Fife.

SHAW, C. J., M.D.Edin., L.R.C.P.Edin., Medical Superintendent at the Arygle and Bute District Asylum, Loohgilphead.

TALLOR, FRANK E., M.D., F.R.C.S., Obstetrical Registrar to Middlesex Hospital.

### Pacancies.

Nottingham General Dispensary—Assistant Resident Surgeon.
Salary, £160 per annum, with apartments, attendance, light, and fuel. Applications to C. Cheesman, Secretary, 12, Low Pavement, Nottingham.
Sussex County Hospital, Brighton.—"Stephen Ralli" Memorial.
A Pathologist. Salary, £350 per annum Applications to the Secretary.

Lewes Dispensary and Informary and Victoria Hospital —Pasidant

A Pathologist. Salary, 2500 per annum applications to the Secretary.

Lewes Dispensary and Infirmary and Victoria Hospital.—Resident Medical Officer. Salary, 2120 per annum, furnished apartments, board, coal, gas, washing, and attendance. Applications to the Hon. Secretary.

The Guest Hospital, Dudley—Senior Resident Medical Officer. Salary, 2100 per annum. with board, residence, attendance, and washing. Applications to the Secretary.

Notts County Lunatio Asylum, Radcliffe-on-Trent, Notts.—Medical Superintendent. Salary, 2500 per annum, with unfurnished house, coal, light, washing, and garden produce. Applications to John Frederick Gell.

Rotherham Hospital and Dispensary.—Senior House Surgeon. Salary, £110 per annum, with rooms, commons, and washing. Applications to the Secretary, H. Helson, Masonic Buildings, High Streef, Rotherham.

London Fever Hospital, Liverpool Road, N.—Assistant Resident

High Street, Rothernam.

London Fever Hospital, Liverpool Road, N.—Assistant Resident
Medical Officer. Salary, £150 per annum, with residence and
board. Applications to the Secretary

### Births.

Howett. - On Jan. 2nd. at 53 Queen Anne Street, London, the wife of C. M. Hinds Howell, M.D., of a son.

### Beaths.

SMITH.—On Jan. 1st, at 173, Blythe Road, West Kenaington, Sidney Smith, M.D., M.R.C.S., late of Bombay, in his 74th year.
WOAKES.—On Jan. 2, at Belvoir House, Farcham, Rebecca Liveing, wife of Edward Woakes, M.D., late of 78, Harley Street, London, eldest daughter of the late Charles Shepheard, Esq., J.P., of Ealing, aged 68.

## Improved Local Applications.

### "CAPSOLIN" (P., D. & Co.)

A combination of oleoresin of capsicum, camphor, turpentine oil, cajuput oil and croton oil with a stable emollient base—agreeably perfumed.

Mode of Use.—Press out a little of the "Capsolin" upon the part affected, and thoroughly rub it into the skin until it is entirely absorbed.

Supplied in collapsible tubes and in tine of 1 pound.

### "EMOLLIENTINE" (P., D. & Co.)

A combination of aluminium hydrate, carbolic acid, isarol, lead oxide, mercuric chloride and sinc sulphocarbolate.

Mode of Use.—Having carefully cleaned and thoroughly dried the part affected, apply the "Emolliantine" spread on lint or cotton wool. If the pain is severe, as in burns and scalds, the application may be renewed every half hour for the first few hours.

Supplied in collapsible tubes and in tine of 1 pound.

### "THERMOFUGE" (P., D. & Co.)

A combination of ammonium iodide, boric acid, menthol, thymol, eucalyptus oil, glycerin and aluminium silicate.

Mode of Use.—Spread a layer of "Thermofuge" about a quarter of an inch thick upon a piece of lint or flannel, and apply direct to the part affected.

Supplied in time containing  $\frac{1}{4}$ ,  $\frac{1}{4}$ , 1, 5 or 10 pounds.

### Therapy.

A valuable counter-irritant which reduces local congestion without vesication. A convenient means of producing the calefacient effect of the old-time mustard plaster in the treatment of pneumonia, pleurisy, muscular rheumatism, neuralgia, etc.

"Capsolin" produces the good effects of an embrocation, liniment, plaster or fomentation, and it is more easily applied, more cleanly, more penetrating and more readily limited to the part affected.

### Therapy.

Antiseptic, astringent and antiphlogistic. Particularly effective in relieving inflammatory conditions of the tissues closely underlying the skin; has proved very beneficial in psoriasis, erythema, sunburn, etc. Used in cases of fissure of the anus, piles, chronic ulcers, intertrigo, pruritus, etc.

Promotes the maturation of suppurative processes, and is an excellent healer of sores. Reduces the pain and inflammation of ulcerated and eczematous surfaces and of swollen joints.

### Therapy.

An efficient antiphlogistic and exosmotic agent, vastly superior to the old-fashioned poultice which it advantageously supersedes in all its applications.

Obviates the application of a painfully hot mass to the skin, and maintains a calefacient action longer than poultices or fomentations do.

Forms an excellent external application in tonsillitis, laryngitis, pneumonia, bronchitis, and pleurisy. May be applied with good results to boils, sprains, swollen joints and various local inflammations.

Please specify "P., D. & Co." on all prescriptions for the above-mentioned.

# Coal Tar Inhaler and Vaporizer.

For Whooping Cough, Croup, Bronchitis, Influenza, and all complaints of the Respiratory Tract,

To successfully employ Coal Tar in the treatment of diseases of the respiratory system, the need is felt of some preparation whereby its active principles can be applied in the form of a vapour.

This need has now been met in Wright's Coal Tar Inhaler and

Vaporizer.

By means of this simple appliance a carefully regulated stream of Antiseptic Tar Vapour can be obtained, combined with pleasantly-scented essences, themselves antiseptic. It affords a ready means of secur ng a direct contact of the vapour with the air passages and acts as a powerful disinfectant and germicide in all diseases where trouble arises from bacilli, &c. The vapour may also be used for general disinfecting purposes.

Write for Particulars, &c., to-

### Notes and Comments.

Under which King?

THE Derbyshire Education Committee have embarked on a new and dangerous policy, to which the attention of the profession should be

directed. It seems that the attendance in the Council's schools has been bad, owing to the ill-health of the pupils, and the Committee have decided on insisting that every medical man who grants a certificate of unfitness to a child shall be in attendance to give evidence at the police court when the parent is summoned for the child's absence. Further by way of greasing the attendance machinery, it appears that they have been sending their school medical officer to patients certified by private practitioners to be unfit for school attendance, and in some cases, at any rate, over-ruling the medical attendant's decision. We find it difficult adequately to express our opinion of these procedures. A family have a perfect right to be guided in the withholding of their child from school by the advice of their own doctor, without any arbitrary interference by the education authority, and it is nothing less than an insult to medical men for the authority to refuse to accept their certificates. Moreover, if a medical officer, usually a younger. and less experienced man, is sent round to revise the decision of such practitioners, a most unseemly position is created, especially if he sees them without consultation with the family attendant. If the ·Committee wish to retain in their own hands the power of deciding which children are fit to attend school, presumably they might, without particular offence, accept only the certificate of their own officer, and make it part of his duties to certify all such cases. But to browbeat and over-ride the family medical attendants by the present methods is preposterous, and we hope that a collective protest may be made in the interest of the dignity and responsibility of the profession.

THE appointment of a bacteriologist A Royal
Bacteriologist.

His Majesty's Household is a welcome sign of the times, and we congratulate Dr. Harold Spitta on being the first converse of the being the first occupant of the new

post. The recognition by the King that bacteriology is so practical a science that he needs an officer of his own to practise it, shows that not only is His Majesty abreast of modern scientific opinion, but that he has greater understanding of, and appreciation for, hygiene than some of his forbears. It is not fifty years since Windsor Castle was discovered to be founded on ancient cess-pools, which must have poisoned long lines of Royal attachés, but, unhappily, were only brought to light when they had slain the Prince Consort, and nearly succeeded in killing the Prince of Wales. Fortunately, the Royal Family and their "dine and sleep" guests are now provided with less sewer-gas than in the good days of old, but in some of the ancient palaces we should old, but in some of the ancient paraces we should not be surprised if there were not an interesting field for bacteriological research. The educative value of the King's example in the matter of the appointment of a bacteriologist cannot but be great, for people will argue that even if the occupant of the post is not so dignified a person as a groom of the chamber or a page-in-waiting, at least he would not have been appointed if bacteriology were not a science having already a very practical bearing on the everyday affairs of life.

Conjunctiva.

THE latest piece of quack-booming From Colliery comes from Scotland, where one to William Miller is extolled as an "eye-doctor" of marvellous powers. Like the bone-setter Rae, this pre-

tentious individual is a miner by trade, and if there is any excuse for becoming a quack, we think, perhaps, the prospect of earning a living above ground, instead of in the bowels of the earth, is the most plausible. To this degree of affluence Miller seems not to have attained, but, thanks to the publicity being given to him, no doubt he will in time. As it is stated that fifty to sixty patients, drawn from the upper classes of the neighbourhood, visit him on Saturdays and Sundays, it is difficult to see why he cannot make a very comfortable living; a good many medical men would be satisfied with that number a week, even if they only paid half-a-guinea a head. When we come to Miller's claims as to treatment, we confess to having less patience with him, for he holds out to cure cataract, ulceration, "dirt tumours," "fire," and "that ungainly inflammation so often the residue of measles." Without pretending to know what fire and dirt tumours are, we may safely say that any unqualified man who holds himself out to cure this list of diseases should be amenable to the criminal law, as the suffering which unskilful and unin-structed "treatment" may cause in the eye is conceivable only by those who have experienced it.

Sea-sick to Order.

THE man, be he medical or lay, who discovers a real preventive of seasickness, of a harmless character, and of universal application, will deserve, and probably make, a for-

tune. In the meanwhile, there are many dabblers, and sea-sickness cures are usually the most evanesscent, of all quack remedies. If every charlatan could only be induced to run one the trade would soon be bankrupt, for however much pleased one or two people may be with the apparent results of a "cure," the bulk of suffering humanity cannot be persuaded that the charm is working to perfection when they

spend most of the voyage pensively leaning over the ship's side. Sea-sickness is often spoken of as a typical neurosis, and it is not a bad thing for some of those who have no sympathy with neurotics to feel the irresistible qualms of this particular variety, for it is a neurosis of an uncommonly real character. It is just reported from Boston that the Allan liner Carthagenian has arrived there after a stormy passage, carrying fifty-seven saloon passengers, who were hypnotised by the surgeon, and that not one of them was at all affected by the movements of the steamer. Credat Judæus. So far we have only telegraphic reports from the city of culture and romance; when the passengers themselves come back we should like a few minutes' conversation with them. Some may have felt benefit from the system; but we cannot be persuaded that not one out of fifty-seven escaped without a qualm.

### LEADING ARTICLES.

### THE REPORT UPON THE INEBRIATES' ACTS.

[FIRST NOTICE.]

It would be difficult to name any social reform in which the medical profession is closely interested of greater importance than that which deals with alcoholism in its many phases. Every legislative effort to deal with the habit certainly deserves our close and sympathetic attention. The recent publication of the report of the Departmental Committee is, therefore, a matter of considerable interest, and we propose to deal with that document at some length. Some of our readers will doubtless recall the terms of the Reference of April 24th, 1908, whereby the Committee were directed "to inquire into the operations of the law relating to inebriates, and to their detention in reformatories and retreats, and to report what amendments to the law and its administration are desirable." On August 17th, in the same year, this was supplemented by an authorisation "to investigate the value of existing methods for the treatment of inebriety by the use of drugs." With regard to this second reference, it may be noted that the manner in which it was interpreted by the Committee, and the impracticable nature of such an investigation, render it of little value. The verdict of the medical profession is the only one likely to be sound and final upon the subject, and no single one of many vaunted "cures" has so far withstood the test of scientific investigation. The Committee have not investigated the methods of treatment by drugs with respect to their efficacy or comparative merits. They merely set themselves to ascertain whether these methods could possibly be used as an alternative to detention, and they report that, quite irrespective of their merits, it would be impracticable to enforce by Act of Parliament any specific mode of medical treatment. The Committee deprecates any further inquiry into the matter, as likely to establish an objectionable precedent; and with this opinion we entirely agree. Turning to the Report itself we find in the introduction a feature that is unique in such a document, namely, a broad and philosophical introduction to the whole subject. After a long experience of such papers, we can safely say, never within our recollection has a Report of the kind been distinguished by so valuable a preface. The plan adopted throughout the Report is to graduate the measures recommended for dealing

with inebriates. In this way it is easy to follow the transition from the mildest methods likely to be of service up to those of the most stringent nature, as may be required to fit the case of the individual inebriate. Two new features of the recommendations deserve close attention. The first is a statutory pledge, breach of which is to form a ground for the application of compulsory control. The second is to institute a guardianship, whereby an inebriate can be controlled without being kept in a retreat; such guardianship may be either voluntarily sought or compulsorily imposed, the latter being the more stringent. Both suggestions appear excellent, inasmuch as they present reasonable alternatives to that summary interference with the liberty of the subject which is apt to be resented by our countrymen. When all these various methods have been tried and found insufficient, it is recommended that the inebriate be sent compulsorily to the retreat. One salient fact brought out by the Report is the failure of the Inebriates' Act, 1898, and the reasons of that untoward result have been carefully investigated. The opinion is expressed that it should be as easy for a magistrate to commit to a reformatory as to a prison, and that the difficulties in the way of such a course should be abolished. These difficulties may be thus briefly summarised and dealt with as follows: -(1) The definition, at present defective, should be replaced by a new one. (2) As to the "three previous convictions," the Committee advise that the present necessity of proving them be abolished. (3) With regard to the refusal of the offender to be dealt with summarily, it is recommended that he should in future be deprived of that option. (4) The abolition of the three years' sentence is advocated, with the substitution of a system of sentences graduated in length according to the repetition of the offence. The Committee further recommend that advantage should be taken of the Probation of Offenders Act by liberating offenders against the Inebriates Act on probation, with or without previous sentence to a reformatory, breach of the conditions of probation being met by a return to the reformatory. Finally, a chapter is devoted to the discussion of the proper authority to be entrusted with the provision of reformatories and the maintenance of inebriates therein, and the extremely important conclusion arrived at is that these functions should be performed by the State, and not by the local authorities. It will be evident to the reader that the tendency of the whole Report is to assume a more thorough control of the inebriates in the interests of the community. deliberate opinion of the Committee is that, in pursuance of that end, the compulsory detention of inebriates is justifiable apart from all question of reformation. In the application of this general principle they have not hesitated to accept its final application to the extent of advising that the detention of irreformable inebriates should be practically permanent. Every inebriate, however, even of the worst and most irreformable character, is to be liberated on probation at the end of three years, subject to a speedy return to detention for another three years if he fails to conform to the conditions of his probation. This is in practice almost an indeterminate sentence, but it is free from the objections to that measure which were pressed on the Home Secretary when the Prisons Bill was before the House of Commons. In conclusion, a word of congratulation may be offered to the Committee on the admirable literary style with which they have

clothed a report dealing with an enormous mass of important facts and considerations.

### CURRENT TOPICS.

#### The Indian Medical Congress.

A good deal of interest is attached to the forthcoming Medical Congress which is to take place in Bombay on February 22nd and the four following days. The subjects set forth for discussion are concerned, for the most part, directly with tropical diseases. Among well-known authorities who have signified their intention of being personally present are Professors Ronald Ross, Kitasato and Musgrave, Colonel Semple, Majors Donovan, Lamb, Smith, and Leonard Rogers, Captains Greig, Forster, Christophers, and Dr. Fowler; whilst others, including Sir Patrick Manson, Sir Lauder Brunton, Colonel MacLeod, Professor Osler, Drs. Nash, Niven, and Ashburton Thomson, will submit papers if they are unable to attend personally. His Excellency the Governor will preside at the meeting, and it is significant of the modern official attitude with regard to medical science that the inception of the scheme came from Government House. The list of Vice-Presidents and of others specially connected with the Congress naturally includes a large majority of Army medical officers. This fact doubtless registers the new era that has sprung up amongst the present generation of medical men in India. There is still a large field open to scientific investigation in tropical diseases, while that of prevention and of sanitary administration is practically boundless. It is to be hoped that the new scientific leaven will permeate all classes and ranks of medical men, whether civilian or military. As regards young India, with its modern claims to increased powers of self-government, there could be no nobler and finer field than that of carrying the Western gospel of sanitation into the houses of their countrymen. There are excellent Indian medical schools, and it is possible for Indians to obtain a professional education without going to the expense of a special training in one of the British centres. The proccedings of the Bombay Congress will be followed carefully by our numerous readers who are interested in the subject of tropical medicine.

Old-Age Pensions and the Senile Heart

ONE of the immediate results of the institution of the Old Age Pensions on January 1st of the present year has a good deal of medical interest. A number of deaths have been reported of aged persons who were entitled to draw their first pension money on that date. Some of these fatalities took place on the night preceding the necessary visit to the post office, some on the morning of the appointed day, and more than one at the office itself. The cause of these pathetic occurrences is not farto seek. The senile heart, under ordinary circumstances, has little reserve power to fall back upon to meet any extra strain that may be thrown upon it. Arteries become thick, and the heart gradually settles down to its routine work, which is kept at a minimum by the natural disinclination of old age to any but the slightest physical exertion. This remark obviously does not apply to the exceptional

aged person whose arteries are healthy and who engages in active exercise, and, it may be, also occupation, until well into a second century of years. Such persons would bear the excitement connected with a pension, or other exceptional mental or physical strain, without damage to their cardiac competency. The difference between robust old age and senile old age could hardly be better illustrated than in the tragedies connected with the first day of pensions for the aged poor. The moral of the matter is clearly that it would be wiser for old folk to get medical advice as to the state of their circulatory apparatus before subjecting themselves to any unnecessary or undesirable strain in connection with their pensions. Further, it would be well for the Government to make the way smooth for all who are shown to be compelled to make their application in person.

Poisoning by Barium Sulphide.

THE use of barium sulphide as a poison must be rare indeed, but an undoubted case was brought to light at a coroner's inquest in Dublin on January and. A woman of intemperate habits, who had suffered from delirium tremens and was frequently depressed in mind, was heard one day to fall on the floor. Her husband and step-daughter ran up to her, and, suspecting poison because of various threats she had made, sent promptly off for a medical man, who seems to have been immediately on the spot. The usual remedies were applied, but without effect, and death took place in a few hours, the patient not being unconscious for some little time. She herself said she had taken poison, and indicated as the agent a bottle of cosmetic fluid, which turned out to contain barium sulphide-this substance being used as a depilatory. Although no analysis of the stomach contents was made, there was no doubt that this salt, and not alcohol, was the operative cause of death. Post-mortem, the brain and lungs were found to be much congested and the heart small and fatty; no very distinctive signs, however, were discovered. This case, interesting as it is from the rarity of the agent used, illustrates the danger which attends the unregulated sale of even apparently harmless hair-washes and similar compounds used for cosmetic and domestic purposes.

Dirty Railway Carriages.

In our last issue we drew attention to the improper heating and ventilation of railway carriages at this season of the year. It is not only in these matters, however, that our railway system leaves much to be desired from the point of view of health. The seats, walls, and floors of the carriages, more particularly third-class carriages, are usually dirty in the extreme. On the main lines, and on express trains, there is some pretence to cleanliness, but on branch lines and the less important trains the condition of the carriages is usually revolting. In third-class carriages spitting is freely indulged in, and apparently-beyond posting useless notices—the companies and their officials take no steps to abate the nuisance. Complaints from passengers are treated with indifference or insolence. The carriages rarely appear to be cleansed. We drew attention to this matter some time ago, in the hope that evidence relating

thereto might have been put before the Royal Commission inquiring into Irish railways, but none of the societies concerned with sanitary affairs in Ireland moved, and it was left to a Commercial Travellers' Association to take the matter up. We do not know whether local sanitary authorities have any power to enforce greater cleanliness in railway carriages, but there is no doubt that the scandal will soon go beyond endurance. As far as Ireland is concerned, we would commend the consideration of this subject to the Women's National Health Association, which has shown so much activity in other directions.

### The Poisons Act.

THE Poisons and Pharmacy Act, which found its way to the Statute Book in the closing days of the autumn session of Parliament, puts a stop, for some time, at least, to a long-standing quarrel between the pharmaceutical chemists of the country and the companies owning drug-shops. It is some years since the House of Lords decided that corporate bodies were outside the penal clauses of the Pharmacy Act of 1868. Since that decision we have had the curious anomaly that, whereas pharmaceutical chemists were tied up by certain legal restrictions, companies could keep drug-stores and deal in drugs without let or hindrance, and without even a single qualified pharmaceutical chemist in their employ. By the new Poisons Act it will be necessary for companies to employ a qualified chemist as manager, and if the company carries on its business in more than one set of premises, then a qualified man must be manager in each. This is a great advance on previous conditions, and though not as radical a reform as some desired, it gives both the public and the pharmaceutical craft further protection. Certain changes in the schedules of poisons are also made by the Act.

### Medical Certificates of Character.

A curious case, which is of interest to medical men generally, was heard at the end of last month at the Westminster Police Court. Dr. F. K. Marsh, of Bradford, was charged with the offence of knowingly aiding a midwife of the name of Inglis to secure unlawfully and fraudulently a certificate of admission to the Midwives' Roll. It appears that Dr. Marsh, who has been in practice in Bradford for many years and possesses a very high reputation there, gave a certificate to this woman that she had been in bond fide practice as a midwife since 1885, and was trustworthy, sober, and of good moral character. As a result of this certificate she was placed upon the Roll, and remained there until 1908, when a report was made to the Central Midwives Board that she had been guilty of negligence and misconduct in the exercise of her calling. Inquiries were then made, and it was found that she had been tried at the Leeds Assizes for murder, on the ground that she had killed a woman by performing an illegal operation. She was convicted of manslaughter and sentenced to three years' penal servitude. It was quite evident that Dr. Marsh gave the certificate in good faith, and, after hearing the evidence, the magistrate dismissed the case against him, but did not acquit him of carelessness. It is essential that medical men should exercise the very greatest care in the giving

of testimonials to assure themselves that the recipients of them are suitable persons. There is no doubt that, either out of excessive good-nature, or, as in this case, from insufficient knowledge of the recipient, certificates are at times given to women who are entirely unworthy to enable them to get positions, or to induce hospital nursing committees to admit them as probationers. The medical profession suffers for this as a body, and, in its own interests, it should set its face against the practice.

Radiography in Non-Medical Hands.

THE medical profession of Paris has been recently exercised by the question as to whether the practice of radiography should be carried on by nonmedical operators. At the request of the French Government the matter has been referred to a Committee of the Academy of Science. As the ill-effects of the rays are manifested upon the human body in a way common to many traumatisms, it will seem to most medical men that such injuries would fall naturally within the province of the medical art to detect, to diagnose, and to treat. Yet for some inscrutable reason practical radiography is to this day left in the hands of non-medical assistants in some of our leading British hospitals. There is some excuse for this practice in remote country places, and also, perhaps, when the radiography is conducted under the close personal supervision of a medical man. As a general rule it is most desirable for any radiographic examination or treatment to be carried out by a medical man, who is trained to recognise the faintest sign of danger, and is charged with a full sense of his moral and legal responsibility. Were the Medical Acts interpreted in favour of the protection of the safety of the public, the responsibility for any mishap that would be cast upon the lay operator would speedily crowd him out of existence. The question is one of some importance to the medical profession, who cannot afford to let much more of their legitimate work drift into outside hands unless they are prepared to find their occupation gone.

The Credulity of Superstition.

THE following passage occurs in a leading article on "Credulity and Superstition" in the Times of the oth inst. :- "The advertisement columns of any provincial newspaper, and of not a few journals of higher repute, show how readily people swallow, with this or that quack medicine, the most incredible tales of its supposed power to cure by a few doses some conglomeration of ailments that has defied doctors for years." We have not examined the advertisement columns of the Times of the oth, but we could easily produce a considerable number of samples selected from a large assortment which exactly answer the description of those objected to in this leader. Two of such have appeared within the last few weeks. Each of these is printed in a conspicuous position next to important reading matter. They vaunt the powers of two medicines which between them profess to cure some forty distinct ailments, including constipation, bladder, kidney and brain diseases, indigestion, insomnia, and mental derangement. Some time ago the Times published a leader dealing with a case in the Courts, and lamenting "that the advertisement sheets of certain publications are continually made

the vehicles of statements which can only be described as preposterous, and frequently as being false to the knowledge of those that make them. It is almost incredible, but nevertheless a fact, that the advertisements alluded to had been appearing all along in the Times, and have since been continued up to now. It is evident that the editors are not aware of what the managers are doing, and the managers are not cognisant of what the editors are writing. It is impossible to believe that the chief proprietors of the Times, whose name stands for all that is fastidiously honourable in journalism, can be aware that, owing to some unfortunate lapse in supervision, their great paper is laying itself thus open to criticism. The Times forms the criterion of journalism. The smallest lapse in its conduct encourages many other inferior papers to "go one worse." In several second in position only to the Times there have lately been appearing enormous and costly puffs of a nostrum denounced more than once in the High Court as a vile imposture. The vast amount of suffering and misery endured by the credulous masses through reliance upon worthless nostrums should be known to the asute editors and men of the world who direct the newspapers. The whole story of cynical quackery has been completely unfolded in the law reports in their own pages, and has been constantly set forth forcibly in all the medical journals, and it is impossible to guess how papers that set themselves up as censors of morals and guardians of the welfare of the people can justify their conduct in carelessly or knowingly abetting a traffic not only fraudulent but cruel to the last degree.

### PERSONAL.

THE QUEEN has given a donation of £1,000 to be expended in the purchase of extra-regulation articles, which will add to the comfort and convenience of sick soldiers in military hospitals at home stations nursed by Queen Alexandra's Imperial Military Nursing Service.

YESTERDAY, Princess Louise Duchess of Argyll attended a matinée of children's plays in aid of the Prince of Wales's General Hospital, Tottenham, and the Kensington District Nursing Association, at the Theatre Royal, Haymarket.

Dr. Marnan, Senior Assistant Medical Officer at Bristol Lunatic Asylum, has been appointed Medical Officer of the like institution at Gloucester.

Ex-President Castro has undergone an operation in the private hospital of Professor Israel, to which he returned from his hotel on January 2nd.

Dr. ALEXANDER ROBB, Medical Officer of Paisley, has been appointed Medical Officer for the Counties of Midlothian and Linlithgow vice Dr. Brock deceased.

Mr. BLAND-SUTTON will deliver the second lecture of the Hunterian Society to-night. His subject is the "Occurrence of Thrombosis and Embolism after Operation on the Female Pelvic Organs."

THE name of Surgeon-General Sir Charles Cuffe, K.C.B., Army Medical Staff (retired), has been placed on the Commission of Peace for the County of London.

THE City of London Lying-in Hospital has received £2,000 from the executors of the late Mrs. A. A. Chippendall Higgin.

DR. LOUIS C. PARKES will deliver the Chadwick Lectures on "The Medical Aspects of Recent Advances in Hygiene as Connected with Sewering," at University College, London, beginning on February 2nd.

THE following gentlemen have been appointed to the Registrarships at the Middlesex Hospital:—Medical, Dr. Otto May, M.R.C.P.Lond.; Surgical, Mr. Cecil W. Rowntree, F.R.C.S.; and Obstetrical, Dr. Frank E. Taylor, F.R.C.S.

THE annual dinner of the West London Medico-Chirurgical Society will take place at the Wharncliffe Rooms, Great Central Hotel, on Friday, February 12th, at 7.30 for 8 p.m. punctually.

At the annual meeting of the League of Mercy, it was announced that a cheque for £19,000 has been handed over to the King Edward's Hospital Fund for London by the League.

THE Essex Parliamentary Committee has approved of an increase of salary from £700 to £800 per annum of Dr. Ambrose, Coroner for the Metropolitan District, as from January 1st last.

THE will of Sir Alfred Pitman, M.D., F.R.C.P., Emeritus Registrar of the Royal College of Physicians of London, who recently died at the patriarchal age of 100 years, was proved last week in the Court of Probate at £10,267.

We are glad to learn that the omission of a medical man from the Midwives Act Committee recently appointed, has been rectified by the inclusion of Mr. F. E. Freemantle, Medical Officer of Health for the County of Hertford.

THE name of Colonel P. M. Ellis has been officially gazetted, to be Surgeon-General, Army Medical Service, vice Surg.-Gen. W. B. Slaughter, retired. Lieut.-Col. R. Jennings, M.D., will succeed to the post vacated by Col. Ellis.

THE late Mr. Harry Barnato's will confirms the report previously published that £250,000 had been bequeathed to "build, equip, and endow a home, hospital, or other charitable institution," in memory of his brother, Barney Barnato, and his nephew, Woolf Joel.

WE offer sincere congratulations to our confrère. Sir James Barr, M.D., of Liverpool, on his rescue last week from a perilous position in the Swiss Alps, where, with his son, he had lost his way in attempting to climb the Niederhorn. The son is suffering, unfortunately, from frostbite.

A CONFERENCE on Tuberculosis will be held at Caxton Hall, Westminster, on February 16th to 19th. Among the patrons are the Duchess of Norfolk, the Duchess of Sutherland, Lord Carrington, the Bishop of London, the Lord Chief Justice, Lord Cross, and Lord Barnard.

THE annual meeting of the Association of Public School Science Masters was held yesterday at Merchant Taylors' School, Charterhouse Square. An address on the relation of general to technical science teaching was given by the President (Sir Clifford Allbutt, K.C.B., M.D.), and Mr. M. D. Hill read a paper on "Anthropometry in Schools."

### A CLINICAL LECTURE

### PNEUMONIA IN THE AGED.

By PROF. R. RIMBAUD, M.D.,

Director of the Clinique at the Faculty of Montpellier.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

THE salient features of pneumonia in the aged are, on the one hand, its gravity and, on the other, its insidiousness, so that it is not without good reason that Grisolle warns us that "we must never forget that in the aged the gravest lesions may be manifested only by a few slight, almost insignificant, symptoms."

With regard to its ætiology this form of pneumonia is associated with the presence of the pneumococcus which, as was shown by Courmont, of Lyons, is commonly present on the tonsils where it leads a saprophytic existence. It is found in the sputum, in the pulmonary exudation, in the pleura, in the pericardium, sometimes even in the meninges. It is readily inoculable in the mouse, and it may be detected on the soiled

garments and linen of the patients.

The contagiousness of pneumonia cannot be questioned, for in hospital wards it is often transmitted from one bed to the next, and indisputable epidemics have been observed in certain asylums for the aged. At the same time its contagiousness is not as pronounced as that of the eruptive Among accidental causes the aged are particularly susceptible to cold, and it is noteworthy that of 156 cases of pneumonia Hourmann and Dechambre met with 109 between December and March. It is sometimes due to traumatism, but this is rare in the aged. Inspiration of dust and irritating vapours has also been incriminated.

Old people obliged to remain in bed owing to paralysis, urinary troubles or injury, are apt to develop pneumonia, though usually of the hypostatic form, but such a patient, if exposed to cold or to pneumonic infection, may develop true pneumonia, and then most frequently on the

right side.

The lungs of the aged, moreover, are more vulnerable than those of the adult. They often suffer from bronchitis and pulmonary congestion, then, too, the rigidity of the thorax hinders proper aeration and favours stasis of the blood, the enfeeblement of the heart and pulmonary emphysema also contribute their part, and with advancing years there is a general decline in the resistance to infective agents. Age is not the only measure of senility, however, for our age is that of our arteries, so that an alcoholic, plumbic or atheromatous subject may be more liable to an attack than one far older, but in better physiological condition.

Pneumonia seems to attack the aged of both sexes indifferently, and the liability increases pari passu with years, and so does the case

mortality.

Pneumonia in the aged presents a rather special symptomatology, but the attack may be characterised by the same symptoms and run the same course as in the adult. As Professor Lemoine observes, there are persons who remain young in spite of sixty years or more, clinically speaking; their respiratory and circulatory apparatus have remained in good state and the brain is clear. In fact, they are virtually adults, and in them pneumonia runs the same course as in the young

As a general rule, however, these symptoms are conspicuous by their absence, there is simply headache, vomiting and more or less pronounced prostration. The initial shivering is often wanting, and in any case is never as marked as in the adult. At most there may be now and again slight feeling of cold, such as is met with in association with pleurisy in the adult. The same may be said of the pain in the side. It is often absent, and when the patient does complain of pain it is usually referred to the pit of the stomach. Dyspnæa. may be quite inconspicuous in the elderly patient, especially in left-sided pneumonia, and this is the more remarkable seeing that we are dealing with emphysematous, cardiac or renal subjects who suffer more or less from dyspnæa in connection with their previously existing malady. Then, too, there is often little or no cough, or, if present, it is moderate, short and dry.

. We must not rely on rusty expectoration in the aged, for many of these subjects neither cough. nor spit and, curiously enough, this is specially the case in grave attacks. Such expectoration as there is is white and stringy, sometimes yellow and streaked with blood. In aged patients the sputum is often greenish in colour, and this seems to be characteristic of pneumonia of the aged. Microscopical examination, however, reveals the existence of the pneumococcus, and shows the sputum to be made up of a mixture of mucus and albuminous exudation with endo-

thelial cells which stamp the diagnosis.

The physical signs are extremely important. While in the adult percussion yields a dull note over the pulmonary lesion, this may be absent in the aged, and may even be replaced by tympanism due to pre-existing emphysema or bronchial dilatation. On auscultation the crepitant rale, often very short-lived in the adult, may be wanting or escape observation, simply because the subject at this stage does not as yet present local or constitutional symptoms which suggest auscultation, so that he often does not come under medical observation at all during the initial stage. By reason of the concomitant bronchitis too the rales are much moister, more like mucous or sub-crepitant rales. breathing is often the first sign to be perceived, but in the aged it is, as a rule, less extensive, more circumscribed than in the adult. also be intermittent, coming and going with great rapidity. These variations are due to the feebleness of respiration, or to the presence of mucus obstructing the bronchi. If the patient be made to cough we may perceive a souffle that would otherwise have escaped notice, and this.

souffle must always be looked for in the axillary region. We must not mistake for a souffle the occasional roughness and intensity of the breath sounds below the clavicle sometimes met with in emaciated aged persons. True bronchophony is rarely met with though the quavering voice of certain subjects may simulate ægophony.

All these physical signs, when present, are very fugitive in aged subjects in whom pneumonia as a rule runs a rapid course to suppuration, grey hepatisation, which is exceptional in the adult.

The temperature in pneumonia of the aged has been thoroughly investigated by Charcot and Dermont, the latter having selected this as the subject of his inaugural thesis. It may run its course without any rise of temperature, but we must bear in mind that in the aged 99° F. is to be taken to indicate a febrile re-action. When the temperature rises, says Dr. Etienne, it usually departs from the classical type by the discontinuity and irregularity of the oscillations. One of the salient features is the tendency to ill-sustained temperatures and rapid decline from a fastigium which may have been quickly reached. The fall is not sharp as in the adult, but is more of the nature of lysis, and may be followed by hypothermia.

The circulatory disturbances are very important. The pulse is precipitate, arhythmic and irregular, with intermittencies, indicative of weakening of the myocardium which may already have been diseased, even before the supervention of the pneumonia, as is often the case in advanced age.

The digestive disturbances comprise vomiting, which often ushers in the attack of pneumonia, a furred tongue which is red, dry, cracked and shiny, all valuable diagnostic signs, and of assistance in prognosis.

The urinary secretion is usually scanty and the urine dark in tint, depositing urates and colouring matter. There may be some albumin, the pro-portion of urea being increased and the chlorides diminished, the latter increasing after the crisis.

With regard to the nervous system there is restlessness or very pronounced prostration. Delirium occurs under three sets of conditions: (1) As an initial symptom soon followed by the classic signs of pulmonary localisation; may come in in the course of a recognised attack, in which case it is delirium of acts and words: (3) delirium may be almost the only symptom, respiration being at most rather more laboured than usual and without fever. Senile dementia may suggest itself, but the dry tongue and ex-Senile dementia amination of the thorax will clear up any doubt.

Clinical Forms.—This description of pneumonia in the aged is the most frequent, most nearly resembling the disease as met with in adults, but in addition to this variety there are several others with which we ought to be familiar. (1) The adynamic form is common in the aged. Enfeeblement and prostration predominate; the pulse is small, irregular and the complexion leaden, the breath fœtid, and diarrhœa copious. The subject is very feeble and indifferent, and succumbs in this state. (2) The ataxic form is mostly met with in alcoholic subjects. There is violent delirium and terrifying hallucinations with tre-mors, gnashing of the teeth and even carphology. (3) The latent form is one of the most interesting varieties. The patient merely complains of vague discomfort with loss of appetite and some muscle ache. The facial aspect changes, and we are

tempted to suspect gastric embarrassment, but the general state becomes worse, the tongue becomes dry, and on auscultation we hear the typical pneumonic souffle. (4) The abortive form is characterised by its mildness and short duration. It generally comes on suddenly with well-marked symptoms, followed by a sudden fall of the temperature, as in the adult. It may recur, but fortunately is usually benign, though if repeated, it may lead to death from cardiac failure. (5) The apoplectic form may simulate an attack of cerebral apoplexy with accompanying hemiplegia. This pneumonic hemiplegia is only met with in the aged, and is probably to be attributed to an organic predisposition, consequent upon previously existing lesions of the bloodvessels of the encephalon.

Course and Termination.—As has already been shown, pneumonia in the aged does not run the cyclic course met with in the adult, If it is to terminate in recovery it progresses slowly, and resolution is delayed, defervescence only taking place towards the twelfth or fifteenth day. Polyuria, sweating and herpes, which usher in the fall of the temperature in the adult, are usually wanting here. The resolution of the anatomical lesion may be incomplete, in which case the general health continues to be unsatisfactory, the typical signs persist, and the lesion tends to chronicity and pulmonary sclerosis. Even after recovery recurrences and relapses are common. nately, pneumonia in the aged for the most part ends fatally. In fatal cases the disease runs a rapid course and soon suppurates. Death is due to the pulmonary lesions which cause asphyxia or constitutional intoxication. Nervous exhaustion may also be a cause of death, which, however, is more frequently due to myocardiac failure. Nevertheless, although the prognosis is grave, it is by no means hopeless, and in any case it is

less ominous than in broncho-pneumonia.

Diagnosis.—The diagnosis of pneumonia in the aged is not difficult, but it must occur to us, if it so often escapes recognition in the aged, it is because the constitutional symptoms and functional signs being so ill-marked do not draw attention to the chest. Whenever we are called to an old man who complains of weakness and digestive disturbances, with epigastric pain, we must look at the tongue, count the pulse and auscultate the chest carefully. If the tongue be dry and the pulse small and irregular, we ought, even before examining, suspect pneumonia. In three-quarters of the cases auscultation will reveal a deep-seated souffle, and percussion more or less dulness, thus confirming the diagnosis.

We must not look for any rise of temperature to confirm the nature of the malady, and in every instance the temperature should be taken in the rectum, which is more trustworthy than in the armpit. In the delirious and the apoplectic also we should think of pneumonia. We must not forget that the physical signs themselves may be lacking, or may be masked by the emphysema, the peculiar resonance of the voice, and so on. Expectoration may be absent, but if present, it should be examined microscopically and cytologically. We shall find pneumococci characteristic endothelial cells. Investigation of the blood is of great assistance, the leucocytic formula with polynucleosis being very characteristic of pneumonia, and we may also succeed in finding the pneumococcus.

Treatment.—Prophylactically we should enjoin avoidance of every possible cause of infection and chill. There is no specific treatment for pneumonia in the aged any more than in adults, anti-pneumococcal serum has useless. All we can do is to maintain the general state and combat the prostration by the aid of alcohol, acetate of ammonium and cinchona. The heart should receive special attention, and we must have recourse to caffeine or sparteine, but digitalis seems to be the best agent of this sort in the aged. It reinforces the heart's action, restores arterial tension, moderates the pulmonary congestion and, more particularly, promotes diuresis, which is indispensable to the elimination of the pneumococcal toxins. way of local measures, mustard poultices and dry or wet cupping are very useful.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by William Taylor, M.B., Dub. Univ., F.R.C.S.I., Surgeon to the Meath Hospital and Co. Dublin Infirmary, etc. Subject: "Cerebral Abecess."

### ORIGINAL PAPERS.

### HOW MUCH PROTEID DOES THE BODY REQUIRE?

BY ALEXANDER HAIG, M.A. AND M.D. Oxon., F.R.C.P.,

Physician to the Metropolitan Hospital and the Royal Waterloo Hospital.

I REGARD it as unfortunate that there is so little precision in the statements of some of those who write on the subject of quantity in food. Thus you may see in a scientific journal such a statement as:
"His meal consists of one or two herrings, some toast, and a cup of milk." This is obviously quite valueless, except as indicating the kind of food the patient likes, and this might have been recorded in three words—fish, toast, milk. If it is worth while to state quantities at all, why not state them precisely? "Some toast" may mean half a loaf, or a three-cornered slice from the toast-rack. "A cup of milk " may mean 5 ozs., if a tea-cup or 10 ozs., if a breakfast-cup. To be of use such a statement should read: "Herring, 6 ozs.; toast, 3 ozs.; milk, 10 ozs."; and from this it is easy to calculate that the meal contained some 630 grains of proteid-a good, useful meal, about half a day's food for a man who only requires 1,300 grs. a day. Yet, from statements like that mentioned, it is sometimes inferred that such a man lives on very small quantities of proteid, and that other people take two or three times as much as is necessary This might be true if the above statement meant: herring, 2 ozs.; toast, ½ oz.; milk. 5 ozs.; but it is very far from being true if the quantities are those previously mentioned, and, as no definite quantities are given, it is open to us to take it either way. What I complain of is, that there is no scientific accuracy about such statements, and that false conclusions are only too likely to be drawn from faulty pre-

But, to come to our question of how much proteid is required. When I was a student, thirty years ago, physiologists taught us that 3 to 3½ grs. of urea must be excreted daily for each pound of bodyweight; and this is equal to from 0 to 10½ grs. of albumen consumed. Then, the Voit standard for labouring-men goes as high as 12, or even 13 grs. per pound. But, more recently, the researches of

Professor Chittenden have suggested to him, and, through his writings, to others, that this is nearly double the quantity we ought to take, and that most people can live well on about 6 grs. of albumen per pound per day. If this is so, the old physiologists were wrong, and the Voit quantities were quite unnecessary. Hence, most of the peoples of the world are, according to such statistics as we are able to collect, at present taking at least 8 or 9 grs. per pound, even when food is scarce and difficult to obtain, thus consuming nearly 50 per cent-more than is necessary. Thus, as Chittenden suggests, a great economy in proteid can easily be brought about.

In these days of increasing poverty and impending famine, it would be a most fortunate thing if these investigations turned out to be correct, and no one would be more pleased than myself if this were so. Though one can reduce the daily turnover of uric acid for a man of 140 pounds from 22 grs. to 12 grs. by shutting out unnecessary xanthins in his food, if this man could live on 6 gre. of proteid in place of 9 grs., the uric acid would be further reduced to 8 grs. per day—1.0 inconsiderable saving in the work of the excretory organs—and he would

live more cheaply as well.

I regret that neither time nor space will permit me to go deeply into scientific physiology, but I will point out in passing that I have for years believed that the celebrated Faulhorn experiment really furnished no proof that force was derived from non-nitrogenous food (see "Uric Acid," Ed. VII., p. 342). Then the theory of nitrogenous equilibrium, on which these recent investigators lay so much stress, seems to me to be almost equally badly founded. For they are here asking us to believe that Nature is little better than a fool, in that, when presented with some excess of that, for her, most valuable substance, proteid, she straightway breaks it up as quickly as possible and passes. it out of the body, and then, when the day of famine comes, she has no reserves. But a very little increase of peristales would pass this excess of albumen unabsorbed, and save all this extensive metabolism, undertaken, so those physiologists tell us, merely for the purpose of excretion. And this is exactly what Nature does in those who habitually overfeed. A little congestion of the liver results in an engorged condition of the veins that empty into it, and then a little increased outpouring of fluid (a constant result of veinous congestion in all parts of the body), with an increase of peristalsis, results in two loose stools a day, and a considerable part of the patient's excess of albumens is passed out unabsorbed, and then the urea excreted by no means corresponds with the proteids swallowed.

Surely it is much more likely that Nature stores for future use any excess of proteid which is given her, and this, as I have pointed out (prev. ref.), has been at least suggested by the work of other physiologists. But, if this is so, I shall be asked, Whence comes the excretion of nitrogen that immediately follows the ingestion of proteid food? The answer, I think, is, shortly, this, that Nature lets go her effete, or partly effete, nitrogen only in proportion as she receives new proteid to replace it. the outgo generally corresponds with the income, and Nature is, perhaps, not quite so foolish as they would have us believe. They have found nitrogenous equilibrium at various levels, because Nature only excretes so much effete nitrogen as she can replace. Then, in absolute starvation, as physiologists have pointed out, she holds on even to the effete nitrogen as long as possible. wonder those who performed the Faulhorn experi-ment on a non-nitrogenous diet did not get a sufficient excretion of nitrogen to account for the force produced. This was no proof that sufficient nitrogen was not metabolised to account for the force produced, but merely showed that Nature, being short of proteids, held on to such nitrogen as she had, in the hope of getting more out of it. Besides this, the excretion of nitrogen in this experiment was only watched for six hours after the labour was concluded, and this, as I know from my own experiments, was much too short a time to clear all the effete nitrogen out of the muscles, even in the well-fed.

The real question is, however, at what level of proteid supply does Nature do the best work, make the best blood, produce the least friction, and the smallest internal expenditure of energy for a given number of foot-pounds of external energy produced?

Fortunately for us, as practical physicians, we can get an answer to this question, which is at once independent of doubtful physiology and easily available for every-day work. We have passing in front of us day by day scores and hundreds of men who are constantly making most interesting physiological experiments upon themselves, and we have only to keep our eyes open and read the results.

Practically, when any normal body is given less proteid than it requires, it first economises—i.e., lives on as little as possible, in the hope that the hard time will pass, and then takes from its own tissues what is absorutely necessary, keeping up bulk, perhaps, to some extent by replacing albumens by fat, and finally, when it cannot get enough proteid from any source, it breaks down. And fats, we may remember, are more likely to be laid down when proteids are deficient, and more likely to be completely combusted when they are plentiful, for, as is well known, animals that have to be fattened must be given diminished proteids as well as increased carbohydrates and fats.

Now, some time before the danger-point of proteid starvation is reached, there are two outward. and visible signs which fly as danger-signals for all who will read them. The first of these is de-pendent on the fact that the rate of the capillary circulation of the skin is the result of two factors: (1) The obstruction in the circulation produced by uric acid in the blood, and (2) the power of the heart muscle. Now, one effect of starvation of proteid approaching the danger zone is diminished vigour of the muscles in general, and eventually of the muscles of the heart, and this brings about slowing of the capillary circulation in the skin, a physiological and pathological sign which I have invented a small instrument (a) to measure.

If the normal rate of the capillary reflux is 6 half-seconds, it may be slowed by such proteid starvation to 7, 8, or 9 half-seconds. For the other signs of this condition, and for the method of distinguishing the slowing due to heart failure from that due to excess of uric acid, I must refer to my books which treat of the circulation. "Heart Failure as the Result of Deficient Food," Medical Record. New York, May, 1906.
The other danger-signal is found in the quality

of the blood, which falls off as absolute proteid starvation is approached. Nature cannot save those from anæmia who are underfed, nor can she make good blood, even with the help of the most powerful drugs, while proteids remain deficients This also I have invented an instrument to measure, namely, a colour-card (b), for comparison with the mucous coverings of gums, lips, and conjunctivæ, from which it is easy to read off the approximate blood quality. If normal is represented by the

(a) Capillary Dynanometer. Hawkaley, Oxford Street, W. Price, half-a-guines. half-aguines.

(b) Colour-Card. Bale and Danielsson, Great Titchfield Street,

W. Price Is.

numbers 1.0 or 1.1 (opposite the darkest colours on the card), people approaching the starvation danger-zone will show colours of .7, .6, or even .5-i.e., less than half the normal colour.

I find, from nearly thirty years of clinical experience, that few people can remain below 9 grs. of albumen per pound without loss in both these directions; their capillary circulation slows, because their heart loses power, and their blood quality falls because there is deficient production of its normal elements.

I may say that this 9 grs. per pound is to be calculated on a quite normal individual not carrying an excess of adipose tissue, as it is his normal muscle structure we have to nourish, and not the adipose he may have put on top of it when he becomes very sedentary in later life. And here there is a source of fallacy and misunderstanding, for it may be said that a person lives on 6 grains of proteid per pound, and this statement may be true in fact, and yet very misleading. Let us take as an instance a woman of middle age weighing 168 pounds; now 168 × 6 equals 1,008 grs. per day; but her real weight, that of her original bone and muscle structure before she became stout, was only 126 pounds, and 126 x 9 equals 1,134 grs. per day; so that my calculation on her real weight only requires this quantity, or but little more, than she is taking. We see, then, that it is quite untrue to say that such a woman is living on 6 grs. per pound; she is really living on 8 or 9 grs. But those ignorant of physiology may be misled into starving themselves by such state-

It has been my fortune to see quite large numbers of people who have been attempting to live on less than 9 grs. per pound, and, with one or two doubtful exceptions, I have never seen anyone who succeeded. I have seen, on the contrary, many who failed and broke down in the attempt, and it was this experiment, constantly repeated, which led me to fix on 9 grs. for the sedentary, and 10 or 101 grs. for the active or hard-working adult. Thus my experiences are in complete accord with the teaching of physiology thirty years ago.

I have also had not a few who came to me, asserting that they were producing much force and living well on less than my quantities, but a collection of urine and estimation of urea in these cases has generally shown quite sufficient urea per pound, and effectually disposed of such claims. These people are under-estimating the quantity and proteid value of the food they eat, which, if they never weigh it, is not difficult to do.

Such having been my experience in a large number of cases over many years, I cannot help thinking that there must be some fallacy about the results obtained by Professor Chittenden, but I shall be prepared to believe them when I have seen cases living for three, four, or more years on 6 grs. per pound of real body weight, and keeping up on this a perfectly normal circulation and a normal blood condition. I know that some of his cases are said to have lived on these quantities for four or five years, but there are no records of circulation and blood-condition before and after.

In conclusion, I can only advise practical workers, who have no time to follow physiological work, which apparently rests on some rather dubious foundations, to leave physiologists plenty of time to work out their various theories, and, meanwhile, to trust to clinical records which are easily made, and have been proved by experience to be reliable.

AMONG the survivors of the recent terrible earthquake at Messina is Professor San Felice.

### SOME REMARKS ON

### INTERMENSTRUAL PAIN. (a)

By J. SPENCER SHEILL, F.R.C.P.I.

ALTHOUGH in practice we are frequently brought face to face with sufferers from this complaint, yet it is surprising how scarce is the literature upon the subject, and how imperfect our knowledge of the

affection is.

We probably all agree that the alleged cause of this troublesome affection is purely conjectural, inasmuch as we have no means of proving that the generally accepted theory that intermenstrual pain is due to an ovarian turgescense is the correct one; nevertheless, if it were not directly connected with the function of the ovaries in producing ova, it would be difficult to reconcile with it the fact that during pregnancy and lactation, when ovulation is usually suspended, regular monthly sufferers from this pain remain quite immune. The pain, too, is commonly complained of in the "ovarian region of Head" or in "the back," though its character tells us nothing, for it appears to be as often "dull and aching" as it is "sharp and cutting."

We do know, however, that sufferers are always at the age of sexual, and therefore ovarian, activity. Some patients are troubled with a vaginal discharge during the period of pain, but I think, in the large majority, this can be traced to some associated affection of the internal genital organs, such as endometritis, and so forth.

There appears to be no connection between intermenstrual pain and dysmenorrhœa, for there are quite as many patients whose menstrual periods are free from pain as those in whom pain is a prominent feature. Yet here is a letter, dated the 16th of last month, from a lady who had suffered from dysmenorrhœa; this latter complaint proved quite amenable to treatment, but you will see that the cure was as bad as the disease, for we learn from her letter that she has substituted intermenstrual pain for the dysmenorrhœa. It is true that this patient is of a highly-strung nature. Time alone can tell if this new development in her is a mere coincidence; it may be but fleeting, or it may have come to stay, if the treatment which I shall speak of later is without avail. Sterility is spoken of as existing in a large proportion of intermenstrual sufferers; this patient, as well as a number of others under my care, has been married some years and, as yet, has not become pregnant. Here is an extract from her letter:—"The period came perfectly up to time and lasted about four or five days. I did not suffer any pain, but about ten or twelve days before I had very bad pains in my back, and felt as if every day the period was going to begin, but it did not start until the proper time.

Intermenstrual pain cannot, I think, be labelled as a mere nervous manifestation, for the class of patient it is frequently seen in is anything but the nervous type; and, moreover, removal by operation of the ovaries has been known to cure cases, which is contrary to what we should expect in merely an ovarian neurosis. If we accept, as I believe we must, the idea that intermenstrual pain is a result of a physiological turgidity of the ovaries, or of one ovary—a forerunner of ovulation and of menstruation—how can we explain why it is that all ovulating women are not martyrs to intermenstrual pain?

This, in my opinion, is best accounted for in this way: the turgidity is due to circulatory changes, and all patients are not alike as regards blood and

(a) Abstract from a communication read before the Obstetrical Section of the Royal Academy of Medicine in Ireland, Dec. 11th, 1908.

blood-vessels. This being so, it will be in the direction of checking excessive, or rectifying abnormal, local or general, circulatory phenomena that our attention will be turned when dealing with the question of treatment.

A good deal of work has recently been done in connection with the relationship between menstruation and calcium metabolism, and it has been shown that there is a considerable diminution in the amount of lime in the systemic blood immediately preceding menstruation, and that lime salts again begin to accumulate after menstruation has ceased; thus, as one would expect the "calcium content" of the blood is at its maximum point about midway between two periods. We know from the teaching of the physiologists the important influence exerted by lime over muscular contraction, especially marked upon the cardiac muscle and the muscular coat of the arterioles. If too little lime is present a weak contractile power results, and vice versa. Is it not probable, then, that indirectly, an undue proportion of lime in the blood may be a factor in the causation of intermenstrual pain?

If ovulation is so active in this class of patient, how can we account for the relatively high proportion of cases of sterility among them? Is the ovum lost in a minute hæmorrhage following upon the rupture of a Graafian follicle from a turgid ovary?

it seems to me quite possible.

As to the treatment of intermenstrual pain, from the literature, and from—might I venture to say—the experience of those of us who have been called upon to treat such cases, we have come to regard "dilatation and curettage," "opotherapy," electricity, &c., as without beneficial effect. If we are willing to assume that circulatory disturbances are the cause, then drugs with a known specific action upon the blood circulation must be the only logical and rational form of treatment.

Professor Stevenson, of Aberdeen, published, some five years ago, observations on the action of salts of manganese in certain forms of menstrual suffering, taking advantage of the well-known effect of these salts upon the circulation in their tendency to restore the loss of normal balance between the arterial and venous systems. In patients who suffer from feelings of undue heaviness, especially marked in the lower limbs, and from dulness and loss of energy, from headaches, from skin eruptions, and from purple tone in the fingers, intermenstrual or premenstrual, we can with some confidence diagnose an abnormal tendency towards equalisation of the arterial and venous blood-pressures, and these are the cases that I have found give such gratifying results under a course of manganese. Of course, if chlorosis or other affection is associated with these symptoms, iron or other suitable drug must be administered also; but iron acts upon the blood, whereas manganese exerts its influence over the blood-vessels. Patients such as I have described almost invariably gain relief by lying down; is not this in itself an argument in favour of a circulatory disturbance being the cause.

Intermenstrual headaches, most frequently complained of in the vertex, though they may be relieved by coal-tar derivatives, will, as a rule, be permanently cured by a prolonged course of manganese, although the same drug may be useless in the menstrual form of headache. The form in which managanese is best administered is the permanganate of potassium, in doses of 2 gr. in pill form, after each meal; but, to do justice to the drug, a course of from four to eight months should be insisted upon, with, perhaps, slight remissions for a day or two, should stomach irritation super-

vene.

If the case chosen for this treatment be a suitable one, relief will follow long before the drug treatment is half over; nevertheless, it would be indiscreet to stop the medicine before six months has elapsed. If it fails, it is still of value as a diagnostic agent, failure turning our thoughts away from functional, and in the direction of organic cause, to account for the symptoms.

Taking into consideration how common a complaint intermenstrual pain is, it seems surprising the scarcity of articles upon the subject that have found their way into the literature. If so little attention and thought has been bestowed on the subject, it is little wonder if we were in a state of comparative ignorance as to its cause. Surely it is worthy of closer investigation. I suggest, if all of us here made careful observations and notes on all such cases as may come under our care for the next twelve months, a fund of valuable information would accrue.

### THE DIAGNOSIS AND TREATMENT

### PNEUMONIA IN CHILDREN.

By G. A. SUTHERLAND, M.D., F.R.C.P.Lond., Physician to the Hampstead General Hospital and to the Paddington Green Children's Hospital.

LOBAR PNEUMONIA and catarrhal pneumonia are the two forms of disease to which I shall refer. Speaking generally, one may say that the former is due to the activity of the pneumococcus, while the latter is dependent on some infective disease in the system which has specially attacked the lungs. Again, speaking generally, one finds that lobar pneumonia affects one lung, while in the case of broncho-pneumonia both lungs are involved.

A method of investigation, which is of extreme importance in the differential diagnosis of these two affections is the observation of the patient when at rest, i.e., when not crying or frightened. I am sure that my older medical colleagues will agree that much is to be learned from quiet observation of the patient. Those not so old will possibly prefer to have the patient stripped at once and attack the chest by percussion and auscultation. My youngest and most upto-date friends will probably reckon both observation and physical examination a mere waste of time, and go straight for an examination of the blood and the opsonic index, while at the same time they will perform lumbar puncture and seek to determine the organism present. All three methods are useful, more especially if carried out in their proper sequence.

Now observation ought to be easily carried out, and the results of observation in a well-marked disease like lobar pneumonia should by this time have been generally agreed to. Yet it is not so. In Rotch's "Pediatrics," published in 1906, I find some remarks on the subject of the symptoms of "Pneumococcus Lobar Pneumonia." (You see there can be no mistake about the disease.) He says: "The alæ nasi expand with each inspiration, and the dyspnœa is marked." There is much authority for this statement, the authority of tradition and many text-books; but does it possess the authority of careful observation?

In lobar pneumonia, during the early stages, i.e., before the critical period has arrived, or symptoms of cardiac or respiratory failure are present, we can observe certain changes in the breathing. It is quickened, it is shallow, it is often panting or grunting, and it is abdominal in type. The rapid shallow breathing is a very characteristic feature in lobar pneumonia, but it is easily overlooked. This rapid breathing is chiefly manifested though the action of the dia-phragm, so that while there is little movement of the upper costal region, a hand placed on the abdomen will feel the quick rise and fall of the abdominal wall in a way which is peculiar to lobar pneumonia and certain disturbances of the central nervous system.

You will read in many books that in children and women respiration is chiefly costal, but I venture to submit that under normal conditions it is chiefly The novelist always makes the heroine abdominal. display her emotions by a heaving chest, and it is necessary for the purposes of a story that she pass her life or such parts of it as are described in a highly emotional condition. But after the story is finished and she has reached the peaceful haven of married life, you would find that her normal breathing was abdominal in type. So with infants and children. They are highly emotional, easily frightened, and under any excitement the breathing becomes costal, but in the absence of any disturbance it is abdominal. Consequently from the rapid abdominal breathing in lobar pneumonia we may at least infer that some factor is at work stimulating the respiratory centre.

To return to the quotation, Dr. Rotch says "the alæ nasi expand with each inspiration." Now, in an excited child, as in an excited horse, the alæ nasi expand without there being anything pathological about it. But in a typical case of lobar pneumonia inspiration is not accompanied by alar movement, so far as I have been able to observe. What is well recognised as a frequent condition is the panting or grunting respira-tion. Observation of this shows an inversion of the ordinary respiratory rhythm from inspiration: expiration: pause, to expiration: inspiration: pause. expiration is panting or grunting, and is a forced movement; the pant or grunt is due to the forcible expulsion of the air through the nostrils or larynx; and this forced movement also frequently produces an expiratory dilatation of the alæ nasi. I admit, therefore, that there is a dilatation of the alæ nasi in pneumonia, but I suggest that it will be found to be expiratory, and not inspiratory. In the absence of panting breathing there is usually very slight alar

movement of any kind.

This point is of importance, further, in connection with Dr. Rotch's next remark—"the dyspnosa is marked." For if inspiratory dilatation of the alæ nasi were present, it would be a strong argument in favour of dyspnœa. One sees the alæ nasi acting and concludes there is dyspnœa, but if the action of the alæ nasi is expiratory that argument falls to the ground. Now, observation will soon convince one that in a typical case of lobar pneumonia in a child there is no dyspnœa. Can one be suffering from dyspnœa and not be conscious of any distress in the breathing? I think not. Observe a child with pneumonia, and you will fail to find any signs of distress in connection with the breathing, if your experience agrees with mine. Coughing, the pain of pleurisy, abdominal discomfort, restlessness—these may all produce a feeling of discomfort and the signs of distress, but in the clinical picture of pneumonia one will not see any evidence of dyspnæa, unless in the later stages, when pulmonary or cardiac embarrassment or respiratory failure is present.

I submit, therefore, that the leading feature of the respiration in lobar pneumonia is an acceleration of the normal rate, with, it may be, some modifications of the normal type. The frequency of the breathing may be increased in ordinary cases to 40, 60, or 80 per minute. It may go higher, and the maximum in my own experience has been 108 respirations per minute. Taking increased respiration in other conditions the maximum I have counted was 120 respirations per minute, which occurred in a case of extreme atrophy or non-development of the brain in an infant, and was presumably due to some interference with the

action of the respiratory centre.

Let us next contrast the respiratory conditions in lobar pneumonia with those seen in catarrhal pneumonia. In the latter the early stage is one of bronchial catarrh, with the appearances due to bronchitis, but soon the extension of the disease into the bronchioles and alveoli changes the picture. presents the signs of obstructed breathing, usually in an increasing degree. We can see that the ordinary abdominal breathing is supplemented by a marked increase in the thoracic movement. The alæ nasi dilate on inspiration, the larynx descends, the clavicles and sometimes the shoulders are raised; there is a sinking in of the soft tissues above the sternum and below the ribs; the sterno-mastoid and scalene muscles can be seen and felt to be acting strongly; and with increasing cyanosis the child may be unable to lie down, and sits up in order to aid the respiratory muscles. This is a picture familiar to all, and it is one in marked contrast to that of lobar pneumonia. The distress and dyspnœa in catarrhal pneumonia are obvious, while in lobar pneumonia they are conspicuous for their absence.

Let us pursue the course of these diseases further. In lobar pneumonia we may have a period of distress and dyspnoza before the crisis, but these are due to cardiac or respiratory weakness which are not evidenced by any pulmonary or cardiac lesions. In other words, one cannot find in the lungs or in the heart any cause for the respiratory distress which may develop in some cases. It may be said that the consolidation of a lobe is a sufficient cause, but this is disproved by the fact that when the crisis occurs the respiration is relieved at once, although the solidity of the lobe of the lung remains unchanged. solidity of the lobe of the lung remains unchanged. In the creeping form of lobar pneumonia, in which lobe after lobe becomes involved, a mechanical factor undoubtedly exists, but this is an exceptional and complicated form. In catarrhal pneumonia, on the other hand, the signs of distress and dyspnœa tend to increase with the duration of the disease, and pari passu the signs of obstruction in the lungs increase. The secretion in the bronchi and bronchioles, and the filling up of the alweder spaces obstruct the and the filling up of the alveolar spaces obstruct the air in its passage to the pulmonary capillaries. At the same time the areas of collapse and consolidation in the lungs obstruct the passage of the blood through the lungs and to the air spaces. Hence follow dilatation of the right side of the heart, cyanosis, and in-creasing dyspucea. In short, the characteristics of this disease throughout its whole course are those of obstructed breathing.

The observation of these conditions in connection with pneumonia in children has aided me very much in the diagnosis. It is usually in the early stages of the disease that a difficulty in the diagnosis arises. At that period also physical signs may be absent and the diagnosis arises. very indefinite in the case of lobar pneumonia, and but slight in the case of catarrhal pneumonia. Further, it will probably be agreed that in both diseases the indications as to treatment on which we rely are supplied much better by the respiratory and cardiac symptoms (dyspnœa, distress, cyanosis, etc.) than by the physical conditions in the lungs as learned by auscultation and percussion.

It is also a common experience that the diagnosis from physical signs only is often an extremely difficult We meet with a considerable amount of bronchial catarrh in many cases of lobar pneumonia, and we meet with extensive pulmonary consolidation in many cases of catarrhal pneumonia. Some even hold that a typical condition of catarrhal pneumonia, so far as the pulmonary signs are concerned, may be produced by the pneumococcus. An excess of physical signs in the lungs may thus render an exact differential diagnosis difficult or impossible, unless the other conditions of the patient and the course of the illness are considered. Also it must not be forgotten that during the whole course of an attack of lobar pneumonia there may be no physical signs in the lungs, although

the other symptoms of the disease are quite definite. I do not propose to consider further the differential diagnosis of these two affections, except in so far as it bears on treatment. It is necessary to have some definite views as to the pathology of these diseases unless one's treatment is to be symptomatic, haphazard and possibly dangerous.

As regards lobar pneumonia, the facts already mentioned, and many others given in the text-books, seem to suggest that we have to deal with a general (pneumococcal) infection, with a local and gross manifestation in the lung, and with a local and symptomatic manifestation in the central nervous system. The general blood infection and the pulmonary lesion do not at present lend themselves to any specific treatment, nor do they in the vast majority of cases call for any treatment at all. The effect on the nervous system is different. It may be described as toxic in character, affecting the whole cerebrum at times, but tending more especially first to stimulate and later to paralyse the respiratory and cardiac centres in the medulla. The character of the respiratory trouble and the tendency to cardiac failure support the view that the medullary centres are involved. It is from the dis-turbance in these centres, and not in the lungs, that danger threatens the patient, and it is to the main-tenance of the vitality of these centres that our therapeutic efforts should be directed.

peutic efforts should be directed.

In catarrhal pneumonia we have probably in all cases, certainly in the majority, a blood infection also, such as measles, whooping-cough, etc., and a local infection in the lung. The general infection is not at present amenable to any direct treatment. The physical signs in the lungs, the nature of the respiratory trouble, and the cardiac embarrassment which ensues, all point to serious impairment of the pulmonary functions. It is the pulmonary affection that is the source of the symptoms and of danger, and it is to the lung condition that our therapeutic efforts must be directed, while at the same time the prolonged and debilitating nature of the illness necessitates general tonic treatment.

TREATMENT.

Certain general lines of treatment are to be carefully followed in all cases of pneumonia, such as rest in bed, warmth, a cool and fresh atmosphere about the patient, and an absence of excitement. Especially would I emphasise the importance of seeing that the patient's body and limbs are kept warm, while the air about him is kept cool and fresh. The former is secured by a sufficiency of blankets and hot bottles, regulated so as not to induce sweating from over-heating. The cult of fresh air has been rather pushed to an extreme lately, and in America young patients suffering from pneumonia are treated in midwinter entirely in the open air, where the temperature may be anything from zero to 40° below it. There is no therapeutic value in breathing air at this temperature. On the other hand, hot air—say above 700—is not so stimulating and refreshing to the patient as air at a temperature of from 62° to 60°, and it is a very good rule to regulate the bedroom temperature accordingly. Very confidently may one assure anxious relatives that the patient will not "catch cold" from breathing such air, and that his personal comfort will be increased, provided the body is kept warm.

The diet in both diseases will be that suited to a febrile illness, and should be characterised by digestibility, simplicity, regularity of administration, and strict moderation as to amounts. Milk, whey, Benger's food and milk, chicken and mutton broths, will be found sufficient during the acute stage. If, however, the appetite is maintained, and the patient will take readily bread and butter, or simple pudding, or an egg, such food will probably be digested satisfactorily. While a febrile patient should not be coaxed to take solid foods, he should not be refused them in the presence of a good appetite. In these pulmonary affections great care should be taken to avoid abdominal distension from flatulence, which interferes with the free movement of the diaphragm. An excessive fluid diet is very apt to induce flatulence.

Stimulation.—In the case of lobar pneumonia, the oung patient will frequently pass safely through the illness without there being any necessity for stimula-tion. When it is called for, the period will be at or about the crisis, and will be, as a rule, short. On the pathological grounds stated above, the stimulation should be directed to the medullary centres, and strychnine and alcohol will be found the most efficient. In the case of creeping or massive pneumonia, in which the whole of one lung, or extensive areas in both lungs, may have become solid, we may find that the available respiratory area has been so much diminished that respiratory distress follows. There is not a sufficient area of surface for the interchange of O and CO<sub>2</sub>. In such a condition the inhalation of oxygen is of undoubted value, as it meets the difficulty of a diminished area of absorption by an increase in the amount of the available supply of oxygen. The indication for its use is cyanosis, temporary or persistent, and the value of the treatment can be quickly decided by its effect on the patient.

In the case of catarrhal pneumonia, stimulation should be directed as far as possible to the lungs and heart. As the disturbance in the latter is chiefly a mechanical one, and due to the obstruction of the circulation in the lungs, it is well to begin treatment with digitalis or strophanthus early in the disease. Alcohol has the disadvantage of tending to increase pulmonary catarrh when given in full doses for any length of time. It should therefore be given in small amount. Oxygen will also be useful in cyanosed patients, and

citrate of caffein is a useful cardiac stimulant.

Local Applications.—It is very doubtful whether local applications have any influence in pneumonic consolidation, and they have the disadvantage of disturbing the patient. Consequently the application of a loose wool jacket, suited in thickness to the season a loose wool jacket, suited in thickness to the season of the year, will probably be more efficacious than many poultices or fomentations. Pleurisy may induce such pain that fomenting or the application of a couple of leeches is called for, but this is exceptional in a patient well nursed in bed. Very few of my cases of lobar pneumonia are treated by local applications to the chest. In catarrhal pneumonia, on the other hand, hot, moist applications seem to serve a definite object in the relief of spasm in the bronchial tubes and conversion in the pulmonary blood-vessels. In object in the relief of spasm in the bronchial tubes and congestion in the pulmonary blood-vessels. In the use of poultices, fomentations, or turpentine stupes, while the intermittent use is beneficial, the constant use, day and night, is, I believe, prejudicial to the patient's progress. Apart from the state of unrest necessitated by the frequent renewal, the desired effect is probably secured by one poultine, and no effect is probably secured by one poultice, and no benefit follows from others continuously applied. One application every four, six, or eight hours, as the case

may be, appears to give better results.

Another method of securing the same result, the relief of spasm and congestion, is by means of a hot bath or a hot pack. The restless and distressed bath or a hot pack. The restless and distressed patient will often sink into a quiet sleep after one of these. In conditions of extreme cyanosis, dry cupping over the back, or blood-letting up to three or four

ounces may be employed.

Steam inhalations require to be used with great aution. The indications would appear to be (1) an caution. absence of secretion about the bronchi; and (2) the presence of spasm about the bronchi. The continuous breathing of steam laden air is exhausting to the patient. The best method appears to be to place a steam kettle at the patient's bedside and to let the steam play over his face for fifteen or twenty minutes at a time. A steam tent is not necessary, and is probably injurious. The custom of keeping a bronchitis kettle steaming in the room day and night is to be avoided, as it produces a heavy and depressing atmosphere, while what we desire is cool fresh air

about the patient.

Internal Medicines.—The consolidation of the lung in lobar pneumonia does not appear to be influenced in any way by medicines, and most of those recommended have the disadvantage of inducing gastric disturbance. A simple febrifuge mixture is probably sufficient in the majority of cases. Many practitioners are of opinion that a temperature of 104° to 106° must be attacked by medicinal antipyretics, but such interference is uncalled for, is useless, and is very apt to have a depressing effect on the patient. The stage of resolution in children usually proceeds rapidly by a process of absorption through the blood vessels. If it seems unduly delayed one may with advantage give small doses of iodide of potash. Coughing in lobar pneumonia may be due to pleurisy, but is more frequently associated with irritation of the terminal branches of the vagus by the pneumonic exudation. Consequently expectorant medicines are not indicated, but rather sedatives, such as the bromides, or paregoric.

In the case of catarrhal pneumonia the indications for drug treatment are supplied by the conditions present in the lungs. There may be hyper- or hypo-secretion. In the dry catarrhal stage, ipecac, the iodides, and carbonate of ammonia are useful. For excessive secretion, belladonna or atropine in an acid

mixture will be found beneficial. Opium is contraindicated because of its depressing effect on the respiratory centre, whereas atropine has a distinctly stimu-It must be admitted that the field for lating action. medicinal therapeutics in cases of catarrhal pneumonia is a somewhat limited one. At the same time, by a judicious use of drugs, and more especially by the avoidance of those which are injurious, one may do a great deal for the relief of the patient.

### CLINICAL RECORDS.

ROYAL CITY OF DUBLIN HOSPITAL.

Case of Pernicious Anamia, (a)

Under the care of ALFRED R. PARSONS, M.D., F.R.C.P.,

#### Physician to the Hospital.

A. B., æt. 45, formerly a fireman on board a crosschannel steamer, came to the Extern Dispensary of the Royal City of Dublin Hospital on September 10th, 1908, suffering from weakness and shortness of breath. His appearance was so suggestive of serious illness. that he was admitted to the medical ward. On inquiry he stated that four or five months ago he had an attack of influenza, and he attributed the onset of his present illness to starting work too soon, because shortly after resuming work he felt a throbbing in his head, and he felt sick till he sat down. A little later he got headache, palpitation of the heart, and weakness in his legs. In spite of these symptoms he continued at work for five weeks, though he felt as if he had a ropeacross his chest and abdomen, and as if his head were bursting. He remained at home for ten weeks, but as he was making no progress he came to the hospital.

Previous History.—He always enjoyed good health,

and had been in the employment of his present company for 35 or 36 years. Till one year ago he acted as fireman; more recently he has acted as a collier.

Family History.—Both parents died aged about 60years. The father succumbed to a paralytic stroke, and the mother to an unknown cause. They had eight children, all of whom were alive except one boy, who succumbed to an accident.

The patient was twenty-one years married. He had

only one child, which died at birth.

Personal Habits.—He chewed or smoked three to four ounces of tobacco weekly. As regards alcohol, he was never a heavy drinker, and for the past three years had taken only an occasional glass of porter.

He took tea at every meal; he has always had a liberal supply of good food.

On Inspection.—He has abundant black hair, but the face is pale and sallow-looking. The lips and mucous membrane of the mouth are very pale, almost the colour of the skin; the teeth are carious in part and covered with tartar; the ears are white. The panicoulus adiposus is slight, but he has not wasted. The nails are white. Veins over back of hand were not visible. Neck showed marked pulsation; a gland on each side was palpable. Thorax was normal, except for a systolic murmur audible over the mitral, aortic and pulmonary areas. There was no tenderness on percussion over the sternum. Abdomen.—The liver was quite normal; the spleen not palpable; and a general examination disclosed nothing pathological. Lower Extremities.—Slight cedema of the ankles; a few cicatrices over the front of each tibia, probably traumatic in origin. The knee-jerks are easily elicited. There is no tenderness on pressure over the calves or the tibiæ; the inguinal glands are just palpable. He has frequently had oozing of blood-stained fluid from his gums, and the bowels are usually constipated. The urine had a specific gravity of 1015; was acid in reaction. It contained neither albumin, sugar, acetone, nor diacetic acid, and only a very small quantity of

<sup>(</sup>a) Read before the Royal Academy of Medicine in Ireland, Dec. 18th, 1908.

indican. On admission the temperature was 98°, and continued in or about normal for a fortnight after. The pulse during the same period varied from 96 to 108.

Blood.—Shortly after his admission, smear prepara-tions were made by the Resident, Mr. Medcalfe, which showed definite poikilocytosis, and such an increase in the white blood cells as to attract his special attenin the white blood cells as to attract his special atten-tion. No other changes were detectable at this stage in the red blood cells. On September 25th a blood count was made, and showed Hg. 20 per cent., red blood cells 1,150,000, colour index .8. Poikilocytosis was still present. I did not detect any nucleated red blood cells, but, with some searching, Dr. O'Sullivan found a few normoblests. found a few normoblasts.

Subsequent History .- In spite of all we could do, the course of the disease, even during the first fortnight, was steadily downwards. He complained of some pain in his right ear, and on September 26th pus escaped freely from the external ear. His temperature rose to 101° F., the pulse to 120. He became stupid and heavy; his temperature rose to 130. F.; he had a sharp attack of epistaxis. On October 6th he seemed to be a shade better, but on the morning of October 7th he got a profuse epistaxis, and died shortly afterwards. A couple of days before his death several blood films were made, which were of exceptional interest, especially in comparison with those made previously, and I asked Dr. O'Sullivan if he would be good enough to make the post-mortem examination. The clinical diag-

nosis was pernicious anæmia. Professor O'Sullivan, who made the post-mortem, said that the appearance of the organs under examination was similar to that found in pernicious anæmia, with secondary septic infection. The heart showed well-marked tabby-cat striation, and the liver contained a large quantitity of iron pigment. The bone marrow also suggested pernicious anæmia. The blood was remarkable and unusual. The earlier specimens showed a definite polymorphonuclear leucocytosis and poikilocytosis, with very few nucleated red blood cells. The blood films, made some days before, as well as those made after death, on the contrary, contained large numbers of nucleated red cells, and a great increase in the number of the white cells. Among the latter were numerous myelocytes. Briefly, the appearance of the organs suggested pernicious anæmia, but the blood removed some days before death was much more like myelogenous leucæmia than pernicious anæmia.

### OPERATING THEATRES.

CANCER HOSPITAL. APPENDICULAR ABSCESS .- MR. BOWREMAN JESSETT operated on a female child, æt. 9, who had been admitted for obscure abdominal pain accompanied by high temperature and constant diarrhea; also a quick pulse and some abdominal distension, with a slight tenderness over the whole of the abdomen. The tongue was furred, and there was some vomiting. The diagnosis was very obscure, and it was agreed to treat the child expectantly, but four or five days after admission considerable dulness was noticed over the right side of the abdomen extending from the diaphragm and liver to a point on a line with the umbilicus downwards, and backwards to the spine. There was no dulness over the iliac regions, and very slight tenderness. The general condition of the child was, on the whole, satisfactory. There was no sense of fluctuation for another three or four days, when it was decided that this dulness was due to a deep-seated abscess, and operation was imperative. Mr. Jessett made a free opening directly over the dullest parters the swelling, and came down on a large abscess cavity, letting out a pint and a half of evilly-smelling He then made a counter-opening in the loin, and passed a large drainage tube through, the end of which protruded from each opening. The patient was considerably relieved. The temperature dropped, but in the course of a day or two rose again to 100° or 101°, the pulse being very rapid. A week afterwards Mr. Jessett's attention was drawn to a large, sausage-

shaped swelling in the left iliac region. This was rather painful on pressure, and fluctuation was thought to be felt. This swelling appeared to be much larger at some times than at others. It was decided to cut down upon it with the idea of its probably being a psoas abscess. On making an incision over the most prominent part of the swelling, a cavity was opened admitting the finger, which could be easily pushed upwards for about 3 ins. along the outer side of the rectus muscle. A small quantity of bad pus escaped. A drainage tube was inserted. Again the temperature dropped, and the patient appeared to be going on satisfactorily; but another swelling formed over the right iliac region. This was opened, and pus evacuated. On passing a probe downwards, this cavity was discovered to communicate with the large abscess on the right side which had been originally opened. The cavity was thoroughly cleansed out, and syringed through with peroxide of hydrogen, and a drainage tube in-serted. From this point the child gradually improved, and eventually made a good recovery.

Mr. Jessett said the case was most interesting and

instructive, as the original symptoms did not in any way point to mischief in the appendix; the fact that the dulness was first discovered below the ribs posteriorly and extending upwards to a level of about the ninth rib, and not traceable downwards to the iliac region, seemed to negative the idea that the abscess originated from the appendix, but the subsequent abscess forming in the right iliac region, he thought, clearly pointed to the supposition that the appendix was the original seat of the mischief. He thought there could be no doubt that this was one of those He thought cases in which the appendix was situated and extended upwards behind the cæcum, causing inflammatory mischief in the retro-peritoneal cellular tissue, which extended upwards towards the diaphragm. The question would arise, he remarked, whether earlier opera-tion would have been advisable, but seeing that there was no sign of any abscess to be found until the dulness was discovered beneath the ribs posteriorly, he questioned very much if the patient would have been placed in a more favourable position if the abdomen had been opened and an attempt made to remove the appendix.

### TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

MEETING HELD FRIDAY, JANUARY 8TH, 1909.

The President, Sir Thomas Barlow, Bart., K.C.V.O., in the Chair.

Dr. James Mackenzie demonstrated his instrument, the clinical polygraph. He said that it had been invented to replace the bulky revolving drum, covered by smoked paper, which had formerly been in use to record cardiac and other vascular movements. By taking the time of the radial pulse as the standard, he had been able, by a comparatively simple instru-ment, to locate the times of various cardio-vascular movements. The essential parts of the instrument were a small cup for receiving the impressions of the pulsations, and a tube for transmitting the impressions to a tambour and lever, the tambour being attached to a Dudgeon and Jacquet sphygmograph. The small cup for receiving the impressions, or receiver, was simply a small shallow metal vessel, circular in shape. The open mouth was applied over the pulsating part, so that its edges were closely adapted to the skin, and all communication with the outer air was excluded. art communication with the outer art was excluded. From the roof arose a narrow pipe, half-an-inch in lergth. To this was fitted an india-rubber tube, 3 or 4 feet long, the other end of which was connected with the tambour. The tambour supported a writing lever about 6 in. in length, and was also attached to the upright stem of a Dudgeon's sphygmograph. this instrument he had taken very many observations,

and had learnt much, but he had found later that inere was often need for a continuous tracing. This had led to the invention of the ink polygraph, an instrument when he was a second of the ink polygraph, and instrument when he was a second of the ink polygraph, and instrument when he was a second of the ink polygraph, and instrument when he was a second of the ink polygraph, and instrument when he was a second of the ink polygraph. instrument whereby tracings of indefinite length, made by ink, could be taken on a gradually unwinding roll of paper. Part of this instrument was a box containing clockwork to move a roller, and so gradually unwind the paper. There were two tambours with levers, one to record the radial pulse, the other the movement under observation. It was fitted with a time-marker, which was also worked by clockwork. Dr. Mackenzie then showed many records which had been taken by the polygraph, and demonstrated the method by which they should be read, and the inferences to be drawn from them. Among other important conclusions he said that he had frequently found a prolongation of the interval between the auricular and ventricular waves in the jugular tracing in advanced cases of mitral stenosis. This he could only ascribe to an alteration in the excitability of the auriculowhich occurred in cardio-sclerosis.

Drs. Mackenzie and Lewis then demonstrated the

method of using the instrument on the human subject.

Dr. Paul Chapman (Hereford) said that he had previously been doubtful whether the times of the various impulses could be definitely measured by Dr. Mackenzie's instrument. He had himself used an instrument by which the venous and other pulsation was adapted to a cardiac record, and not, as in that of Dr. Mackenzie, to a radial pulse record. His own method required more skill to obtain records of any value. He had now no doubt that the sequence of events was as Dr. Mackenzie had described, and believed that the sequence of events was as Dr. Mackenzie had described, and believed the sequence of t lieved that the instrument shown was of great value i.1 correlating cardiac and vascular records with the signs found by other means of clinical investigation.

Sir LAUDER BRUNTON said that the subject was full of difficulties. He admired greatly Dr. Mackenzie's skill and patience in obtaining these records, and his ability in deciphering them. He thought that the polygraph would help much in the diagnosis and in the application of medicines to cardiac disease. He had used several recording instruments, but considered this the most convenient, though less expensive than many he already possessed.

Sir JOHN BROADBENT did not understand the reason for the explanation given of the delay in ventricular contraction in cases of mitral stenosis. He thought that it might be explained in another way. As the crifice got narrower and narrower, it naturally took more and more time for the blood to get through, so that the delay could be explained on a purely physical basis. He questioned the use of the term nodal rhythm. In many cases of old-standing rheumatic heart disease, and in the hearts of old people, there was often considerable general fibrosis, so that it would be very difficult to differentiate the auriculo-ventricular bundle.

Dr. Herringham paid a high tribute to Dr. Mackenzie for the work which had led to his putting forward this new method of examination, although he did not accept without question all that Dr. Mackenzie had said.

Dr. THOMAS LEWIS said that the prolongation of the interval between the auricular and ventricular systole could not be explained mechanically. During the taking of a record this change would often occur quite suddenly. For twelve months he had used the method under discussion, and thought that the examination of irregularly-acting hearts was futile without it.

Dr. MACKENZIE, in reply, said that, at this stage, it was no longer always necessary to take a tracing. His explanation of the irregular rhythm, which he had called nodal rhythm, was purely hypothetical, although he had given many reasons for it.

THE United States Ambassador in Berlin, on behalf of Mr. Carnegie, has handed to the bankers of the Robert Koch Fund, for the campaign against tuberculosis, a sum of £25,000. The fund now has a capital of £57,500.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, DECEMBER 18TH, 1908.

The President, Dr. A. R. PARSONS, in the Chair.

CASE OF PERNICIOUS AN.EMIA.

THE PRESIDENT read some interesting notes on the clinical history of a case of pernicious anæmia in a fireman of a steamship. This case will be found fully reported in another column, under the heading of Clinical Records.'

In the discussion that followed,

Dr. J. MAGEE FINNY thought the condition during life pointed rather to leucæmia than to pernicious anæmia. Every addition that could be made to their knowledge on the subject was most interesting. In a case which he published many years ago, the iron stain was found also in the kidneys.

Dr. MOORHEAD quoted two cases as showing that there must be a large number of cases of pernicious anæmia in which the nucleated cells suddenly burst out into the blood in the last days of life, and more particularly when any acute infection occurred.

Dr. TRAVERS SMITH said that if the man's illness. could be traced to mastoid disease, or if the original source of the septic infection was in the middle ear, there would be no necessity to explain the matter as pernicious leucæmia or anæmia. An elevation of temperature was not necessary in order to develop a leucocytosis. The nucleated red cells were not numerous, and possibly they and the myelocytes that appeared were compensatory to the marked hæmolysis

that was evidently going on.

Dr. BOXWELL referred to a case in which it occurred to him that the anæmia was due to a parasitic infection. He did not improve on treatment with arsenic. After two months he suddenly got much better, and he left hospital with about 65 per cent. of red cells, and hæmoglobin considerably over. In a second case he found a number of things in the blood of which he was not sure. They were like either lymphocytes or loose nuclei. In a third case—of a woman who got well, but returned to hospital and died—the postmortem showed uniformly fatty organs, with iron stain in liver, spleen and kidneys. They all had bad teeth, and the second case had an extremely septic condition in his mouth.

The President, in reply, said the case presented, from a clinical point of view, what he would call the typical aspect of pernicious anæmia. The man had no trouble from his ears or mastoid cells. There were no ear symptoms whatever until fourteen days after admission to hospital, and he believed the infection occurred while in hospital. The case might, perhaps, be put into the ill-defined group called leucanæmia, but the weight of evidence was in favour of pernicious anæmia.

Professor O'SULLIVAN, in reply, said that in thick parts of a preparation the cells sometimes became shrunken in the slow-drying, and it often became impossible to distinguish between a lymphocyte and a nucleated red cell. The difficulty did not occur in a thin preparation. There was no naked-eye appearance thin preparation. of iron in the kidneys.

CASE OF TUBERCULOSIS OF LUNGS, WITH TUBERCULOUS

TUMOUR IN CEREBELLUM.

Dr. O'CARROLL read notes of a case of above in a girl, æt. 19, who was admitted to the Whitworth Hospital on May 12th. From Christmas, 1907, she began to have dimness of sight, and later complained of occipital headache and vomiting. Her sight became worse. There was no relation between the vomiting and food. The tongue was protruded slightly to the right. There was no marked difference in the expression of the two sides of the face. She was quite intelligent; her speech was slow and slightly slurring. There was no discharge from the ears. Both knee-jerks were well marked. There was no actual wasting of flesh, and the menstrual function was right. She improved very much in hospital; but in October, during his absence from town, she complained of headache, and had bleeding from the nose. Her temperature rose; she became somewhat comatose; and lumbar puncture was performed on November 9th, about 30 cubic centimetres of fluid being withdrawn. She improved a little for a few hours, but died on November 16th, after several days in a state of coma.

Dr. PURSER said that during the performance of lumbar puncture she shrieked with headache, but it ceased in about ten minutes. At the post-mortem the only organs showing disease were the cerebellum and the lungs. He was aware that the upper lobe of the right lung was consolidated, but he was not aware of anything being wrong with the left lung. In it, how-ever, they found an enormously thickened pleura, and the whole lung was riddled with cavities. It was most remarkable that with such extensive disease of both lungs there should be so little symptoms. The patient at no time had any cough.

SPECIMENS FROM A CASE OF RICKETS.

Dr. Purser exhibited specimens of a case of rickets from a child, æt. 14 months, who had been suffering from measles, and had died from bronchial pneumonia, following measles. There were marked symptoms of rickets in the wrists, ribs, and cranium. It was rather unusual to see the changes in the ribs, and still more so in the skull, which showed enormous thickening of the parietal bones.

CARCINOMA OF STOMACH AND LIVER.

Dr. EARL showed specimens of carcinoma of the stomach and liver taken from a woman who had been in hospital only a few hours. At post-mortem the liver was found very much enlarged, and it contained so many nodules of cancer that at first sight it looked somewhat different from the ordinary secondary cancer of the liver. He found in the stomach an ulcer, which lay on the posterior wall over the pancreas. Part of the edge of the ulcer was sharply cut and terraced. He could find no other cancer in the body as a primary

Dr. TRAVERS SMITH said the woman was æt. 36. She complained of violent pains in her epigastrium, which had come on two days previously, but before that she had had no stomach symptoms. She had taken a considerable quantity of alcohol, but there were no ascites present. He examined her for a primary carcinoma, but found none.

NOTE ON BISMUTH POISONING.

Mr. Gunn read a note on bismuth poisoning.
Dr. Walter Smith recalled the history of the toxicology of bismuth. Apart from its simple mechanical effects, observations from a physiological point of view showed that it produced the phenomena of irritant poisoning. There were abundant experiments showing that bismuth produced just the symptoms to be expected from its alliance with the arsenic and antimony groups.

There were several deaths on record, so that it was a

drug not to be used recklessly, and he thought the surgeon should desist from using the sub-nitrate. Dr. HAYES said a good many cases of poisoning had been recorded by radiographers from the use of the sub-nitrate. Patients had died of overdosing, and the deaths were said to be due to the toxic effects of the nitric acid liberated. The shadow of the nitrate was denser than that of the carbonate.

Mr. Gunn replied.

### CORRESPONDENCE.

#### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

### FRANCE.

Paris, Jan. 10th, 1909. CORYZA.

CORYZA, or common cold in the head, is, in general, a benign affection, but it may sometimes be attended with serious consequences, by extension of the inflammation to the neighbouring parts, hence the advisability of treating it. The treatment is either abortive or palliative.

The abortive treatment, if it has any chance of being successful, should be applied at the outset, that

is to say, when there is yet but a sensation of dryness and heat in the nasal fossæ. It must be of short duration (half a day), otherwise it becomes useless creven dangerous, according to Prof. Lemoine.

Preference should be given to inhalations; aspiration of vapours of ammonia, eau de Cologne, tincture of iodine, menthol.

Brand advises:

Phenic acid, 1 dr. Liq. ammonia, 1 dr. Proof spirit, 2 dr. Water, 4 dr.

A few drops on blotting paper, inhaled several times during half a day.

Abortive powders are more active: --

Cocain, 10 gr. Menthol, 5 gr. Salol, 4 dr. Boric acid, 4 dr.

A pinch of the powder snuffed up every hour. Or:

Salol, 2 dr. Salicylic acid, 30 gr.

Tannin, 15 gr.
Boric acid, 1 oz.
Irrigation of the nasal fossæ succeeds very well in cutting short rhinitis, but it requires some patience on the part of the patient, as it is rather disagreeable at the beginning. A tablespoonful of chlorate of potash or boric acid is dissolved in warm water, previously boiled and passed through the narines by means of Weber's syphon or the douche of Esmarch. The patient should not expose himself to the cold air for two or three days after the irrigation.

An excellent practice is to paint the mucous membrane as high up as possible, with a solution (1—10) of cocain and glycerin. Ruault jugulates a cold in the head with benzoate of soda, given internally, a drachm during the day for children and two drachms for adults. Weitlauer, recommends the use of salicylate of soda

and Dover's powder:

Salicylate of soda, 1 oz. Dover's powder, 40 gr. Ess. of peppermint, 1 drop.

Mix and divide into twenty powders; one every four hours. This treatment, he says, will procure a rapid cessation of the irritation: it is both preventive and

The palliative treatment covers a series of little measures, all more or less useful. When the secretion is abundant, clear and liquid, it is very irritating, producing a very disagreeable local malaise. At this period, atropine can render service at the dose of a quarter of a milligramme (1/256 gr.). It should be suppressed as soon as the secretion becomes more consistent, when one or other of the following powders may be substituted: -

Cocain, 2 gr. Morphia, 2 gr. Tannin, 2 dr. Salicylate of bismuth, 4 dr.

Cocain, 1 gr. Boric acid, 1 oz. Fuller's earth, 1 oz.

Or: Cocain, 2 gr.

Camphor, 10 gr.

Powdered sugar, 2 dr.
A mixture of menthol (20 gr.) and olive oil (4 oz.) is very refreshing, and is commonly used.

Ointments are preferred by Prof. Lemoine, as they

insure antisepsis of the nasal fossæ:-

Camphor, 30 gr. Vaseline, 3 dr.

Or:

Or:

Menthol, 2 gr. Vaseline, 3 dr.

Or:

Salol, 6 gr. Vaseline, 1 oz

Or (combination):

Menthol, 6 gr. Boric acid, 30 gr. Salol, 4 gr. Cocain, 4 gr. Vaseline, 1 oz.

For the headache accompanying coryza, the following wafers :-

Valerinate of quinine, 6 gr. Pyramidon, 3 gr.

Antipyrine, 10 gr. For one wafer; one to three a day. ARSENIATE OF STRYCHNINE.

Arseniate of strychnine is exceedingly useful in certain chronic pulmonary affections such as chronic pronchitis, asthma, emphysema, and in broncho-pneumonia of the aged, by reason of its almost specific action on the contractibility of the muscles of Reissesen. Given in pills or injections at the dose of from 1/33rd to 1/10th of a grain, arseniate of strychnine raises the tone of the lungs and gives relief as no other treatment can.

#### ECZEMA.

Weeping eczema is quickly healed by applications of coal tar by means of a camel-hair pencii, and left to dry as long as possible (from 20 minutes to half-an-hour), after which the place is powdered with any absorbent powder (Fuller's earth). Two or three days afterwards the application is repeated, and perhaps once again, but rarely four applications are necessary. Zinc ointment completes the cure.

The only inconvenience attending this treatment is that, by reason of the colour of the ingredient, it can-not be applied to exposed parts, face, neck, hands. Otherwise, all the patients submitted to this treatment express themselves content.

GERMANY.

Berlin, Jan. 10th, 1009 At the Medizinische Gesellschaft, Hr. Rosenstein showed a large number of figures of epidiascopic projection of preparations of TUBERCLE OF THE KIDNEY.

The preparations were all taken from cases that had been operated on by J. Israel. The speaker distinguished three forms of the disease (a) the ulcerous cavernous form, (b) that of tuberculous ulceration of the apices of the papillæ, (c) the chronic nodular form; these different forms could, however, only be distinguished in their early stages. In order to distinguish the form b at the operation it was necessary not only to expose the kidney and make an explora-tory puncture, but to open widely. The speaker expressed the hope that as functional diagnosis became more perfected, the chronic form would be diagnosed so early that total extirpation of the whole organ would be no longer necessary, but the partial resection would be enough to ensure perfect recovery.

Hr. Orth pointed out that the pathological anatomist often enough saw tuberculous disease of the kidney in the early stage that had given rise to no clinical symptoms at all. He recognised Israel's division into different classes. The first commencement of the disease was found in the medulla or in ment of the disease was found in the medulia or in the calices at the spot where the mucous surface was reflected about the apices of the papille. The early appearance of the disease in the medulia was explained by the appearance of tubercle bacilli in the straight canals; in the glomeruli the bacilli must be excreted from the blood in acute miliary tuberculosis.

Of great importance as regarded the development

of renal tubercle was tuberculosis of the walls of the arteries. In this the lumen of the artery might be arteries. In this the lumen of the artery might be blocked by an infarct which afterwards became tuberculous, and from this tubercle might develop in the whole of the region supplied by the artery. Tubercle bacilli had been found in the canaliculi without the kidneys themselves being diseased (Benda), but of course the patient must have already been infared.

EXPERIMENTAL INQUIRY INTO THE INFLUENCE OF MINERAL

WATERS ON THE SECRETORY FUNCTION OF THE STOMACH.
At the same meeting Hr. Bickel contributed a note on this subject. He had performed experiments on several dogs with gastric fistulæ, and also on a girl

with an esophageal fistula made in consequence of atresia of the æsophagus from swallowing corrosive liquid. Food swallowed passed out again through the opening in the esophagus unless conducted through a tube into the opening in the stomach. A similar operation was performed on the animals experimented on. In this the speaker believed he had excluded a number of sources of error, but he was not optimist enough to think that he had excluded all.

In his experiments he had made use of representa-tives of all the groups of mineral waters that had been employed in the treatment of gastric troubles, giving a risumt of the results obtained. Although these may not be at once applicable to normal digestive processes, they form a basis for more exact

inquiry.

Changes in the Digestive Tract in Pernicious ANÆMIA.

A short note on this subject occurs in the Deutsche Med. Zeitung, 102/08, communicated by Drs. Faber and Bloch. They say that in pernicious anæmia a diffuse gastritis is often present, in which there is a tendency to atrophy of the glandular tissues, with, as a clinical symptom, gastric achylia. Disease of the intestine is not a constant concomitant, and especially there is no atrophy of the bowel, inflammation, or degeneration of the glands. Whatever the relationship is between the gastritis and the anæmia it cannot be taken that the former is the direct cause of the disease.

Gastritis with achylia is frequently met with in patients having no tendency whatever to anæmia, and in many cases of well-pronounced anæmia there was no achylia, and most probably only a very slight degree of gastritis. As it cannot be thought that the anæmia itself causes the gastritis, it may be assumed that the two are caused by the same irregularity.

The probable explanation is that the anæmia is produced by some poison generated in the system. Possibly the gastritis may arise from an effort on the part of the stomach to get rid of the poison. The intestinal tract is the part in which it may most naturally be assumed that the poison originates. When it has been determined that the bothriocephalus latter may set up a perpicious angulate and that the latus may set up a pernicious anæmia, and that the same may be said of strictures of the bowel there need no longer be any doubt on the matter.

## AUSTRIA. Vienna, Jan. 10th, 1909.

FLAT AND CLUB-FOOT.

SEMELEDER gave the Gesellschaft a description of what he called a new theory of the formation of flat and club-foot which many of the members thought was common knowledge. He set out by saying the very act of standing was performed by first fixing the hip and knee-joints, leaving the ankle as the pivot of movement, but this joint only having a perpendicular movement the centre of gravity passes through this to the heel, but if any undue force alters this, an unnatural rotation takes place and a torsion of the foot is produced, either eccentric or concentric to the axis. first symptom of these altered forces is a relaxation of the pedal muscles, producing flat-foot, which is an eccentric rotation not depending upon a habit, but an inherent force of the muscular action, or some injury like compression that produces an elastic strain on the joint. He compared the leg to an elastic prop, flexible at hip, knee, and ankle. If the centre of gravity be carried behind the knee-joints it will necessarily act adversely on the ankle-joint, forcing it outwards; if the centre be outside the knee, the fulcrum is altered and turns the foot inwards.

Benedikt said there was a good deal of truth in the argument, but he did not think the articular distorsion was so simple, nor the cause so easily explained.
EXTRACT OF THE HYPOPHYSIS.

Pál gave a brief account of his experiments with an extract which he obtained from the hypophysis of bones. By intravenous injections of the extract a temporary description in the blood proving the blood provin porary depression in the blood pressure takes place

which is rapidly followed by a rise. It resembles adrenalin in its action, although antagonistic in the renal vessels. When applied to the eye it is mydriatic in its action on the pupil. Its action on the vessels is the same as occurs with pilocarpin, which causes a dilatation, which in the renal arteries is very pronounced.

WASSERMANN'S SYPHILITIC SERUM

Bauer and Meier gave a minute description of the lechnique and efficacy of Wassermann's serum, which they had used in 381 cases with great success. In 28 genuine cases of syphilis the reaction was perfect. In the first reaction of 35 doubtful cases, 31 of them reacted as genuine syphilis, the other two as asepsis and carcinoma.

In cases of florid syphilis the reaction was perfect in 85 per cent., but not so frequent where the syphilis was over one year old. Its action was positive with greater certainty in cases of cachexia than in the robust. In other 28 cases where control experiments were conducted, 25 were positive. They believed that in all cases of syphilis it was characteristic except the lepra form, which were not constant. To obtain good results, strict attention to the technique was necessary. Salomon thought this specific reaction of Wassermann was not free from many objections. Kraus said there was little objection to the use of the serum, but its theoretical importance could not be clearly explained.

Porges questioned the advantages of Wassermann's serum, as many febrile diseases, diabetes, tumours, and tuberculosis all gave a sort of positive reaction.

LEAD POISONING.

Teleky presented two females with abnormal localisation of lead poisoning. Both of the females are bottle cleaners, which have composite capsules. The paralysis is in the muscles, usually not affected in the muscles of the thumb. Rold presented a cooper, æt. 41, with lead poisoning, but the ætiology seemed buried in obscurity. He was greatly emaciated, anæmic, and the typical pulse. In the urine small quantities of lead were present, and in the blood were granular red blood corpuscles; the latter symptom, though not a constant sign present, is irrefragable when met with.

Teleky said there were so many peculiar sources of lead poisoning that it would be difficult to conjecture the origin. It was found in children's toys, "paprika," and drinking utensils.

ANEURYSM OF BASILAR ARTERY.

Wiesner demonstrated a saccular aneurysm which had split the pons and deformed the right side of the medulla oblongata.

Chvostek gave a clinical history of the case. He said the patient was healthy up to a year ago, when he complained of headache, followed by vomiting, vertigo, deafness, imperfect vision, difficulty in swallowing and speaking. There was paresis in the left side of the body, paralysis of the right abducens and internus, and distinct paresis in the left abducens and uvula, with increased reflex on the left. There was no congestion of the fundus of the eye. The association of the paralysis of the ocular muscles while the motor nerves were intact pointed to what was diagnosed as central tubercle in the pons varolii.

## FROM OUR SPECIAL CORRESPONDENTS AT HOME.

#### SCOTLAND.

THE LATE DR. ARGYLL ROBERTSON.—A telegram was received in Edinburgh on January 4th announcing the death at Gondal, India, on Sunday, of Dr. Argyll Robertson, the well-known oculist. A full account of his career will be found in another column, under the heading of "Obituary"

UNIVERSITY OF EDINBURGH.—From the annual report the past year has been a prosperous one in point of number of students, which is the highest attained for 17 years. The total matriculated students were 3,328 (including 595 women), distributed among the faculties thus:—Arts, 1,156 (505 women), Science, 295 (16 women); Divinity, 62, Law, 304 (3 women); Medicine,

1,490 (59 women); Music, 21 (12 women). Of the students of Medicine, 45 per cent. were Scottish, 19 per cent. English, 9 per cent. Irish, 5 per cent. Indian, 20 per cent. from British Colonies, and 2 per cent. foreign. Thus the proportion of non-Scottish medical students is well maintained; in particular the number of Colonial students exceeds by 34 the highest number reached at any time during 20 years. Among new Lectureships instituted is one on the History of Medicine (Dr. J. D. Comrie); the lectures will be delivered during this winter and next summer session. Dr. G. M. Robertson has been appointed Joint Lecturer with Dr. T. S. Clouston on Mental Diseases. There have been three changes in the professoriate during the year: Professor Caird has replaced the late Professor Annandale, Professors Walker and McKinnon have succeeded Professors Crum Brown and Taylor. A number of changes have also taken place on the staff of lecturers: Dr. Harold Pringle succeeds Dr. Herring, of lecturers: Dr. Harold Pringle succeeds Dr. Herring, Dr. Jolly succeeds Dr. Sutherland Simpson, Dr. Melville Dunlop succeeds Dr. Burn Murdoch, Dr. Marshall succeeds Dr. Arnott, and Dr. Alex. James succeeds Dr. Affleck. The principal structural changes have been in the direction of adapting to new purposes the rooms vacated by the Natural Philosophy and Engineering departments on their transference to the new laboratories in Infirmary Street. A much felt want has been met by the provision of a second examination room. The recataloguing of the library having ination room. The re-cataloguing of the library having been completed in 1906, and the alphabetical arrangement of the entries and insertion of the cross references being also practically complete, the question of the printing of the catalogue falls to be seriously considered. No funds are available, but perhaps some generous donor may be found willing to associate his name with this work.

### LETTERS TO THE EDITOR.

RHEUMATOID ARTHRITIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—I am greatly indebted to the somewhat advanced "Student of Sixty" for his kindly remarks respecting my clinical lecture on this subject. I sincerely trust that if perchance he has not already passed his "Final," he will find it useful in that trying ordeal. He is evidently a man of great discernment, who has cultivated to their fullest energy his powers of observation, and I wish him well. I am afraid that the talk about "radio-activity" in certain natural hot springs is based on no solid foundation, and that it is but the outcome of a passing fancy. There is no doubt, how-ever, that much of the improvement seen in rheumatoid arthritis cases is due to the warmth of the climate and to basking for many hours a day in the bright sun-shine. The only question is where is it to be found in its fullest splendour. I know Aix-les-Bains well, and in summer it is hot enough in all conscience. For winter there is no place like Algiers, and Mustapha Superieur is an ideal health respecially if one can "cool off" by a few weeks spent at Hammam R'Irha, which is high and bracing, and where the sun ever shines. Then there are opportunities of availing oneself of the train de luxe on the Oran-Tunis line, and of visiting all kinds of quaint and interesting cities, changing, if my memory serves me, at El. Guerrah for Biskra, the desert outpost. Algiers has many advantages over Egypt, not only in accessibility, but in the cost of living.

Undoubtedly much depends on the nature of the soil, and sand or gravel are preferable to clay; but if there is a full south exposure, and the town is placed on the slope of a hill a clay subsoil is no disadvantage.

slope of a hill, a clay subsoil is no disadvantage. The great objection to our English health resorts is the expense necessarily incurred at anything like a decent or so-called first-class hotel. At many of these they refuse during the season to quote inclusive terms even for a prolonged stay, and 25s. a day is the average charge for room and board, even when that room is at the top of the house and of the size of a fairly capacious wardrobe. The wines, too, are atrociously dear, and of a want of character which is beneath contempt, whilst the cooking is pretentious and void of dis-

tinction. At the hotels at Aix-les-Bains good accommodation, good food, including decent red or white wine, can be obtained for from 15 to 18 francs a day, whilst in Algiers the same necessities can be secured for even less. Under the circumstances it is hardly surprising that many British patients, especially if travelling with their domestic belongings, prefer the Continental life. The increased cost of the journey is soon defraved by the reduced hotel bill. Possibly soon defrayed by the reduced hotel bill. Possibly when the English hotel keeper realises this, he may regain some of his lost customers.

I am, Sir, yours truly,
WILLIAM MURRELL.

January 8th, 1909.

THE APPENDIX: ITS USE, ABUSE, AND ITS CLAIMS FOR PROTECTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—I have only to-day seen a notice of Mr. C. B. Keetley's article to the Lancet in the Daily Mail of yesterday, and, whilst admiring his ingenuity and scientific suggestion—viz., that the appendix should be detached in certain cases where asepsis is within the bounds of possible permanent maintenance. the bounds of possible permanent maintenance, so that it may wander at will through the intricacies of the general peritoneal cavity, I fear it may not often be practical. This suggestion, admirable as it may be,

does not appear to me to be altogether practicable.

I also notice that a medical correspondent from the West London Hospital, in a contemporary, suggested that the appendix should be treated in a similar way to the gall-bladder-viz., by establishing an opening through the muscular layer of the abdominal wall, either temporary or permanent. No doubt in certain favourable cases the latter procedure is good surgery, and in competent hands excellent results have been chtained.

I would, however, humbly remark that when comments are made in the lay Press on any article taken from a medical paper, such as the Lancet, British Medical Journal or Medical Press, the language should be so simple as not to confuse the lay public with such terms as "appendicicostomy."

In these days of advertising of wonderful cures effected by patent medicines and manipulations, all doubtless containing a certain admixture of truth, it is most important that a noble profession like ours should keep itself clear. We never hear in the lay Press of the failure of these remedies or of these manipulations. On the other hand, we in publishing our statistics in our societies, or the medical papers, should, and do, I believe, publish our failures as well as our successes, for the good of the profession and the public who read them.

It was said many years ago by an eminent surgeon at a clinical lecture delivered at the London Hospital, that the chief use of the appendix being placed in the position which it occupies was to put fees into surgeons' pockets, and when the appendix boom was started in America it was even suggested in that great and progressive country that the appendix should be removed at birth or soon after, at the same time as vaccination, and in the case of the male child concurrently with circumcision when advisable.

I believe it was Knowsley Thornton who was the first

prominent surgeon to make the statement in this country that the gall-bladder in the normal state in a healthy man or woman during life should contain no bile, but had the power of secreting a peculiarly viscid mucus, which was controlled in the amount of the secretion and discharge by nerve action on the powerful muscular wall, to act so as to assist the passage of bile down the common duct.

Most of us have observed the inverted oil bottles, generally half-full of some special lubricating oil, placed at certain points of those magnificent engines of the boats plying between England and France, etc., and, in my humble opinion, the function of the appendix may be looked upon as acting at the junction of the large and small intestine as a special lubricator for the prevention of constipation, the most usual exciting cause of appendicitis, in the same way as the gall-bladder.

We are all too fond, or too apt in our own particular way, to make clean the outside of the cup and platter, whilst an overloaded inside is ravaged by the various bacillary wolves lying in wait at various spots along the tortuous canal, which measures at least 55ft. in length, and reduced into yards represents 1/95th part of a mile

May I close this letter by repeating the words of the late Sir William Jenner, delivered many years ago at the College of Physicians :-

'It is the duty of the physician (including, of course, the operating surgeon and the general practitioner) to prevent disease, and, failing that, to cure disease, and, failing that, to alleviate suffering and prolong life."

I am, Sir, yours truly,
WILLIAM ROSE.

10, Queen's Gardens, Lancaster Gate, W., January 5th, 1909.

#### PARENTS AND CHILDREN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. Sir,-Those who like myself invariably scrutinise your excellent paper from cover to cover are often rewarded by discovery of an interesting paragraph in outlying regions. This week, for example, on your last page, I find a reference to an article in a woman's magazine on "Modern Over-culture of Children." Parents, children, and doctors are nowadays all undergoing rapid character changes. The buxom mother, a picture of mental and physical health and happiness, surrounded by her brood of six to twelve bonny bairns, is becoming more and more rare; and the family doctor, the trusted confidential friend and adviser of the parents, knowing their history, and the history of everyone of their progeny intimately, is becoming equally difficult to find. The French fashion of limiting the children to two or three has made enormous strides among our well-to-do and wealthy classes within the past twenty years. Facts. regarding the falling birth-rate have been constantly commented upon in your pages. Not so much notice has been anywhere taken of the psychological effects upon both parents and children; they are none the less remarkable and interesting. When families were less remarkable and interesting. large the parents—the mother especially—had no time to closely watch the movements of the children; they were left much more to themselves, and to the experience and discipline which naturally developed among the small crowd. The mother's influence, neverthe-less, predominated; and where this was of the wholesome sort emanating from a woman of the sterling British type, the breed of physically fit was usually morally superior. Nowadays the two or three children are tied to the mother's apron string if she is devoted to them; or completely neglected and handed over to the care of servants, if she belong to the "smart set," that places the pursuit of pleasure as the supreme object in life. Every observant practitioner with ex-perience extending over the last 25 years must recognise the changing quality of the child and of the young man and woman of the day. The customs which have produced certain types in France, are producing like effects among our own people. A process of evolution is going on. But evolution does not connote necessarily the creation of a higher type; it may be merely better adapted to its environment. If that environment involves a moral atmosphere of pure egoism, the ultimate results surely must be disastrous.

I am, Sir, yours truly,
A YORKSHIRE PRACTITIONER.

Jan. 9th, 1909.

#### EXPERIMENTS ON PATIENTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,-My attention has been called to certain remarks with the above heading in your issue of January 6th last. In answer to the City Coroner's question as to the meaning of the words, "no experiments on patients," which is always printed on our reports, I

replied: -- "I should say it simply means exactly what it says-that there are no experiments-although, I suppose everything in treatment is in the nature of an experiment to a certain extent. In view of the fact that some people among the poor are very superstitious and shy of hospitals, I strongly advise every hospital to put the same words in their reports. They are of a reassuring nature. It means, practically no experiments, which are for the sake of knowledge, rather than for the good of the patients." And I concluded by reiterating my advice that other hospitals should adopt our custom. The last part of my reply is omitted from your paper. As far as "vivisection" (as defined by the 1876 Royal Commission) is concerned, no question of vivisection or anti-vivisection need necessarily come into experiments. You can experiment otherwise than for treatment without "vivisection."

If this Battersea General Hospital, quite apart from It this Battersea General Hospital, quite apart from any innuendo which hyper-sensitive persons may discover, and without any "quandary," as far as it is aware, thinks well to reassure those who, with or without actual evidence, are shy of entering a hospital, so that within its walls they may feel absolute confidence and safety, it has a perfect right to do so, without being absurdly and illogically told that it thereby asserts that there are no other hospitals where such appears are never indulged in; and that it stands experiments are never indulged in; and that it stands alone in this particular!

I am, Sir, yours truly, GEORGE W. F. ROBBINS, Secretary.

National Anti-Vivisection Hospital, Battersea Park, London, S.W., Tan. 8th, 1909.

[We publish the above as we do not wish to be thought unfair, and because we are content to leave the question to the judgment of impartial people.—ED.]

### VENTILATION OF RAILWAY CARRIAGES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—The question of the ventilation of railway carriages, I see you have considered deserving of attention among your articles on "Current Topics" in this week's MEDICAL PRESS AND CIRCULAR. It is one of those questions which belongs rather to that speciality which we recognise as sanitary engineering; for ventilation is hardly a subject which comes within the province of medical science. At the same time it is more than probable that sanitary engineering would not take up this subject unless it were forced upon it by the medical profession, and by our medical journals. You conclude your article in the following words: "The ventilation of railway carriages in winter depends primarily on adequate heating arrangements, and we cannot think how the public, year after year, allow the railway companies to flout their health and comfort with supercilious disdain."

A few years ago I made some observations on the air conditions of railway and other carriages, as their ventilation seemed to be misunderstood and neglected. Railway carriages and omnibuses are both unhealthy when at all overcrowded, and the means used to ventilate them show great ignorance. I will give you one instance of this which is constantly before us. on most of our lines a curious kind of double-pointed, small, chimney-top looking apparatus stuck on the roofs of most carriages, and when we are inside a carriage we at once associate these "ventilators" with the round openings we see over our heads. If we look closely into the way in which these ventilators work we must be surprised to see that some are set so that they point towards the engine, while some are set at right angles and point across the carriages. As I knew the theory on which this ventilator was constructed and patented, it certainly surprised me that any engineer could have brought out this article and that the railway engineers could have taken it up as they have done. The conclusion I came to was that railway engineers knew nothing about the science of ventilation, and that we need expect no improvements in the ventilation of railway carriages until this ignorance was replaced by some accurate and scientific study of the subject. What I learnt most from was experiments made with one of Casella's anemometers on the movements of the air inside railway carriages, when the windows were more or less open, and when the train was moving at slow or rapid pace. One thing certainly impressed me, and that was that those openings which we see just above the carriage windows, and which we can close or open by moving a slide that is made for the purpose, are of no use, for when I held the anemometer over these openings the fan wheel did not turn either way, and practically this arrangement was, and is, of no use. It sometimes amused me to see a passenger jump into a carriage and close the ventilator for fear of cold.

Some simple plan of warming carriages could easily be supplied by railway engineers; but ventilation is not such a simple matter, and I hope that your article will lead to this subject being treated with attention by the great railway companies, as it is to their advantage to study the comfort and health of their

passengers.

I am, Sir, yours truly, ROBERT LEE, M.D.Cantab.

Pwllheli, N. Wales, Jan. 9th, 1909.

### OBITUARY.

DR. ARGYLL ROBERTSON, OF EDINBURGH.

FROM a telegram received last week, we were made aware of the sudden death of this well-known oculist, at Gondal, in India. The unexpected end to his career in a distant country came as a sad shock to a wide circle of friends, for although Dr. Robertson had been in somewhat failing health for the past year, he was not known to be dangerously ill until the news of his death was received.

Douglas Moray Cooper Lamb Argyll Robertson was born in Edinburgh in 1837. He came of medical stock, for his father was a surgeon of high standing, and occupied the presidential chair of the Royal College of Surgeons immediately before Mr. Syme. Dr. Argyll Robertson was educated at Edinburgh and abroad; he

graduated M.D. at St. Andrews in 1857, and became a Fellow of the College of Surgeons in 1862. From the time he entered the medical profession he specialised in ophthalmology, being led thereto by the fact that his father, though not a specialist, had devoted much attention to eye diseases, and by the influence of v. Graefe, then at the height of his fame, under whom Dr. Argyll Robertson studied during his reise jahren in Germany. One of Dr. Robertson's first original discoveries in his speciality was made in conjunction with Sir Thomas Fraser on the properties of calabar bean, in which he found the agent he had long been seeking which was capable of causing myosis when applied locally to the eye. As a writer in "Quasi-Cursores"—the tercentenary festival volume of the University—says:—"A few years later (1869-70), he had again the good fortune to add another stone to his own cairn by associating his name with the eye symptoms in certain spinal lesions, and the 'Argyll Robertson pupil' is now as much a classic name as either Bright's disease or Pott's fracture." In 1870 he was appointed ophthalmic surgeon to the Royal Infirmary, and remained on the acting staff until 1897, when, on his retirement, he was appointed Consulting Surgeon. He was also Honorary Lecturer on Ophthal-mology, and held numerous other honorary appoint-ments in Edinburgh, notably those of Ophthalmic Surgeon to the Blind Asylum and to the Sick Children's Hospital.

Dr. Argyll Robertson was an ardent follower of every form of manly sport, in which his fine physique every form of many sport, in which his his physical enabled him easily to excel. He was one of the leading amateur golfers of his day, winning the gold medal of the Royal and Ancient Club five times, and the silver cross twice. He was also a member of the Royal Archers-the Royal Bodyguard for Scotland. Next to golf, travel was his chief recreation. He had already visited Japan and India, and it was on his return to the latter country, on a visit to the Thakore Sahib of Gondal, that he died.

Among the numerous honours which Dr. Argyll Robertson's high position in the profession brought on him the following may be mentioned:—Honorary Surgeon Oculist to the King, President of the Ophthalmological Society of the United Kingdom, of the International Ophthalmological Congress, 1894, of the Edinburgh Medico-Chirurgical Society, of the Royal College of Surgeons; member of the Ophthalmic Society of Heidelberg, Corresponding Fellow of the New York Academy of Medicine, Honorary Member of the Neurological Society of New York, Foreign Associate of the Society of Physicians of Prague. In 1896 he received the degree of LL.D. from the University of Edinburgh. Dr. Argyll Robertson married, in 1882, a daughter of Mr. Fraser, of Tomavein and Findrach; he had no family. On his giving up practice in Edinburgh in 1904, he and his wife removed to Jersey—a step which was regretted by the large circle of friends who owed so much to the hospitality of Dr. and Mrs. Robertson. At that time he was presented by his colleagues with a portrait by Sir George Reid, R.S.A., and a replica was hung in the College of Surgeons.

### DR. ALEXANDER PATTERSON, OF GLASGOW.

Dr. ALEXANDER PATTERSON, an eminent Glasgow surgeon, died on January 5th, at Draperstown, Ireland, his native place, to which he retired a short time since when relinquishing practice in Glasgow. Dr. Patterson graduated M.D. of Glasgow University in 1854, where he proved himself an apt and successful student. In 1860 he became F.R.C.S.Ed., and in 1869 a Fellow of the Faculty of Physicians and Surgeons, Glasgow. Soon after graduation, he started practice in the east end of Glasgow, and in 1868 was appointed Dispensary Surgeon to the Royal Infirmary. He became Surgeon to the Lock Hospital in 1872. When the Western Infirmary was opened, a deputation of the managers waited on him and asked him to become one of the surgeons. Dr. Patterson was recognised as the most dexterous surgeon in Glasgow in his day, operating with equal facility with either hand, and an enormous amount of surgical work passed through his hands. He held it to be impossible to overcrowd his wards, as he insisted on the windows being kept freely open night and day, and patients before they got accustomed to this mode of life used to grumble a good deal. He was thus a pioneer in the fresh air treatment of disease, and his results compared most favourably with those of his colleagues. Nay, he told the writer that patients coming into his wards with old bronchitic What he coughs frequently left cured of their cough. practised in the hospital, he practised at home, for his bedroom window was raised at the bottom nearly a foot and had never been shut for twenty years, except by window cleaners. He regarded oxygen as the best of all tonics. He early adopted Lister's treatment and practised it most successfully. There was no safer surgeon than Dr. Patterson. He was a man of rare sagacity, and he diagnosed a case promptly. He had great faith in the use of the cautery for white swelling in the knee-joint, coupled with an iron splint, with a raised U-shaped curve to allow dressings to be applied. He taught that both tubercle and cancer were local expressions of constitutional states, and that measures to raise the vitality of the patient were as necessary as surgical operations. He had a large experience of syphilis and considered it a disease that was very seldom completely eradicated, having known local manifestations of it thirty years after infection. In phagedænic sores, he gave half to one grain of opium every four hours, a practice also recommended by Erichsen, and which appears to act like a charm, when conjoined with cleanliness.

Dr. Patterson was a faithful observer of Nature, and made many acute and original observations. He was the first to cut down on the kidney and remove a stone from its pelvis. He tells how he was a little nervous, lest hæmorrhage should be troublesome. He had great faith in putting diseased parts at rest, by splints or otherwise, and insisting on free and thorough drainage. He was a man of rare surgical wisdom and instinct, and was often called in consultation with colleagues; but he was more than a great and successful surgeon, holding strong Christian principles, by which he en-tirely subordinated worldly honours and emoluments to his firm conviction of Biblical truth.

DAVID THOMAS CADVAN JONES, M.B. THE death is announced of Dr. David Thomas Cadvan Jones, Colwyn Bay, at the age of 33 years. The son of the late Rev. Cadvan Jones, Congregational minister, Carmarthen, he was educated at Caterham Congregational College and Aberystwyth University College, and took his M.B. degree at University College, London. His first practice was at St. Leonardson-Sea, which he relinquished in order to remove to Colwyn Bay, where he resided for four years with his mother and two sisters. Dr. Jones was one of the most popular and useful members of the Colwyn Bay National Eisteddfod Committee.

### DR. REGINALD ROBERT WHISHAW, B.A., M.B., F.R.C.S.

WE regret to learn that Dr. R. R. Whishaw died at Willowburn, Queensland, on December 10th from an accident, at the early age of 46.

Dr. Whishaw studied at the University of Cambridge and St. Thomas's Hospital. At the University he obtained the B.A., M.B., and B.C. degrees, whilst in London he qualified for the Fellowship of the Royal College of Surgeons and as a licentiate of the Royal College of Physicians. In medical appointments, Dr. Whishaw had a wide experience, for at various times he held the following posts:—House Physician to the Brompton Consumption Hospital, Surgeon to Croydon Hospital, Demonstrator of Anatomy at the Medical Schools of Cambridge and Bristol, House Surgeon to the Liverpool Children's Hospital, and Secretary of the London and Counties Medical Protection Society. Dr. Whishaw subsequently practised in Tasmania, whilst at the time of his death he was medical superintendent of the Hospital for the Insane at Willowburn, Queens-

ELIZA M. CURRIE-SMITH, M.B., B.S.Lond. WE regret to announce the death of Miss Eliza M. Currie-Smith, M.B., B.S.Lond., who was appointed in February last to the post of Junior Assistant Medical Superintendent at St. Pancras Workhouse Infirmary. She died at that institution on Tuesday last, after a few weeks' illness. She was trained at the Royal Free Hospital. Patients, nursing staff, and medical officers will long retain recollection of her charming personality and kindly disposition. Among the wreaths was one from the infirmary patients, who subscribed their pence as a token of affection and esteem for the departed officer.

### REVIEWS OF BOOKS.

CLINICAL BACTERIOLOGY. (a) Wz welcome the appearance of a new edition of this admirable work. It is only some two years since the last edition was published. The book is specially designed for the use of the general practitioner, and is divided into two distinct sections. The first of these deals with bacteriological technique, and contains one of the simplest accounts of this subject with which we are acquainted. Not only does the author supply his readers with the information necessary to carry out the various processes, such as staining and mounting films and sections, but he also shows how to apply the results obtained in making a diagnosis. The very lucid and accurate account given of the preparation

<sup>(</sup>a) "Clinical Bacteriology and Hæmatology for Practitioners." By W. D'Este Emery, M.D., B.Sc. Lond., Clinical Pathologist to King's College Hospital and Pathologist to the Children's Hospital, Paddington Green. Third edition, London: H. K. Lewis. 1908. Price 7s. 6d. net.

of culture media is a special feature, and at the same time the mode of developing the cultures themselves is fully and clearly explained. In the section devoted to hæmatology, which is much the shorter of the two, a sufficiently complete and practical account is supplied of the methods adopted in these days for the investigation of diseases of the blood. A brief description of the mode of preparation of bacterial vaccines has been added to this edition. Fuller details are now given regarding the diagnostic method of lumbar Some of the coloured plates have been redrawn, and one or two new figures inserted in the text. The book, as it now stands, is one of the best guides on clinical bacteriology and hæmatology that the practitioner can have. Throughout its pages he will find the solution of many difficulties which crop up in the course of one's private work in connection with these subjects.

CLINICAL LECTURES ON NEURASTHENIA. (a) NEURASTHENIA is unquestionably receiving more attention and occupying a larger place in works on systematic medicine than it did-doubtless owing to the fact that its ætiology and treatment are now better understood. To the author, we believe, belongs the credit of first pointing out, in 1898, that a large proportion of cases of neurasthenia—probably 75 per cent.—are due to a toxemia of some kind; indeed, the reason why these cases have so often been regarded as incurable is the difficulty of discovering the particular

toxemia in operation for purposes of treatment.

The author's view is that in a large proportion of the cases the toxemia is of gastro-intestinal origin, though the symptoms are often so obscure as to escape recognition. The existence of a psychic element, however, is not overlooked—in fact, a new chapter has been added dealing more particularly with the psychology and the psychotherapy of the disease. This strikes us as one of the best chapters in the book, for the author handles the subject sympathetically, and gives some very useful advice concerning the difficulties encountered in dealing with these patients, and how best to cope with them.

The fact that a fourth edition has been called for at so short an interval is evidence that the subject is one of general interest, and we know of no better guide to its diagnosis and treatment than Dr. Savill's masterly

### MEDICAL NEWS IN BRIEF.

### University of Lenden.—The Medical Unit in the Army.

THE Military Education Committee appointed by the Senate on December 16th to manage the University Contingent of the Officers' Training Corps, have received the reply from the War Office to the offer of the University to furnish a contingent of the Officers' Training Corps. The Army Council have sanctioned Training Corps. The Army Council have sanctioned the formation of a contingent which shall include an infantry, an engineer, and a medical unit, these units being composed of three companies of infantry, one company of engineers, and two sections of a field ambulance respectively. It is expected that additional companies will be formed at a later date, subject to the sanction of the Army Council. The rules for the contingent provide that admission to the contingent shall be restricted to gentlemen who are members of the University of London, or are non-matriculated students pursuing a regular course in schools of the University, save that, subject to such regulations, if any, as may be prescribed by the Military Education Committee, power is reserved to the Commanding Officer in special cases to admit gentlemen who, though not comprised in either of the foregoing categories, are desirous of gaining the certificates of proficiency obtainable in the Officers' Training Corps The Corps is intended for the preliminary training of young men with a view to their qualifying for commissions in the

Special Reserve of Officers, or the Territorial Force, and membership of the corps is restricted by the Army Council to British subjects of pure European descent. The members of the medical unit will be drawn from the medical schools attached to the University, more than a hundred students from Guy's, St. Bartholomew's, St. Thomas's, University College, King's. College, and other medical schools naving already applied for membership. Enrolment in the contingent was to begin immediately after the Christmas vacation. With regard to headquarters, no arrangements have yet been made, and the training will be carried out, for the present, in the colleges attached to the University.

#### The Allegations Against a Middlesbrough Medical Man.

The Allegations Against a Middlesbrough Medical Man.

THE adjourned inquest on Amy Arnold (25), single woman, of Smeadon Street, North Ormesby, Middlesbrough, was resumed at North Ormesby on January 6th. At a previous inquiry grave allegations. were made against a well-known Middlesbrough medical practitioner. The girl Arnold died at North Ormesby Hospital on December 3rd, following an alleged illegal operation. At a previous inquiry the medical gentleman against whom the allegations were made gave evidence, stating that he did not remember made gave evidence, stating that he did not remember any one of the name or description of the girl having called upon him, and said that practically all the state ments made against him were untrue. He also denied the truth of statements made to the doctors in the hospital by deceased. The adjournment was for the purpose of submitting to the public analyst a quantity of medicine found at deceased's home.

The Coroner (Mr. O. H. Cochrane) said he did not propose to take any further evidence that day. There was a lot of additional evidence to be gone through. Dr. Falconer, who was present at the death of Arnold, had unfortunately been called away to the funeral of a relative, and, taking that into consideration, he thought it best to adjourn the inquest to some future

### Accommodation for Infectious Cases at Bootle.

AT a recent Council meeting at Bootle, Alderman Cain, Chairman of Bootle Health Committee, proposed, "That the terms offered by the Liverpool Corporation for the admission of small-pox cases from Bootle into the Liverpool City Hospital at Fazakerley be not accepted, and that the scheme for the establishment of a small-pox hospital, approved on February 5th, 1908, be proceeded with." He stated that, following upon the Local Government Board inquiry into the matter, a communication was sent to the Health Committee asking them to try and make some arrangement with the Liverpool Corporation to take in their small-pox cases. This had been done, but the charges which Liverpool made were so exorbitant that the Health Committee could not recommend them tothe Council for their acceptance. The committee, therefore, wanted to go on with their former scheme, which had not been refused by the Local Government Board. If the consent of the latter was not granted, Bootle would have to pay at once an annual sum of £500 to the Liverpool Corporation whether there were any patients from Bootle in their hospital or not.

Dr. Wild seconded, and said it was absolutely necessary that they should have some extra accommodation for small-pox. The expense would be very little at

Dr. Rafter protested, on behalf of the public, against the proposed erection of a new infectious hospital, and maintained that it was not required.

Dr. Turner moved as an amendment that the schemebe put back for further consideration. His principal reason for this, he said, was absolutely one of economy.

Alderman Ascroft said there would be a great outcry in the town if the scheme was carried out.

Alderman Cain said he would like to know what the people of Bootle would think if, when a severe epidemic of small-pox occurred, the health authorities were to send all the scarlet fever patients to their homes in order to make room for the small-pox cases

at the present infectious hospital.

The amendment was carried.

<sup>(</sup>a) "Chinical Lectures on Neurasthenia," By Thos. D. Savill' M.D.Lood., Physician to the West End Hospital for Diseases of the Neurous System, &c., &c. Fourth edition. London: H. J. Glaisher. 1908, Price 7s, 6d. net.

#### Consumption In Dundee.

A PROPOSAL has been made and inquiries instituted thereanent for the Corporation of Dundee taking steps for thoroughly dealing with the subject of consumption. The importance of dealing with the disease has been emphasised, and the time has now arrived, in the opinion of several members of the Council, for seriously tackling the subject. The opinion in the country is in favour of making consumption a com-pulsorily notifiable disease. The idea in the minds of certain members of the Town Council is that the Sanatorium at Auchterhouse should become a Corporation institution. Meantime, inquiries are being prosecuted, and a visit is to be made on behalf of the Public Health Department to obtain data on which future proceedings may be based. The Sanatorium at Auchterhouse, it may be mentioned, occupies a site at the base of the Sidlaws. Founded by the generosity of the late ex-Provost Moncur, its present dimensions and development exceed expectations. In 1899 he gave a sum of £10,000 for the purpose, but this was subsequently found to be insufficient to meet requirements, and Mr. Moncur at various times increased the amount of his gift until the total reached about £25,000. It was opened on September 26th, 1902. Much good work has been done through the agency of the institu-tion, but it has always been found difficult to make the revenue from patients' board and contributions from private sources meet the cost of maintenance.

#### Old-Age Pensions and Infirmary Patients.

THE Local Government Board, Ireland, have informed the Letterkenny Guardians that old-age pensions are inalienable, and that, therefore, they cannot be taken by Guardians to pay for the cost of the maintenance of the pensioners in a workhouse infirmary.

#### The Irish Medical Association.

AT the last meeting of the Council of the Irish Medical Association a circular recently issued by the Registrar-General to Registrars of Births and Deaths in Ireland was under consideration. This circular requests Registrars to send to the pension authorities a weekly return of the deaths of all persons aged 70 years and upwards. A fee of two pence is to be paid for each return, in addition to a fee of two pence for every death entered in a return. We understand that a memorial has been sent to the Lords Commissioners of the Treasury praying for adequate remuneration, failing which the Registrars may have to consider whether they can continue to act in that capacity under the present conditions. The Council of the Association adopted the following resolution:-

That the Council of the Irish Medical Association. beg to inform the medical profession in Ireland that there is no statutory duty cast on them in regard to signing certificates as to the inability of pensioners to attend at post-offices for the purpose of receiving payment of their pensions.

"The Council are also of opinion that members of the medical profession signing certificates in connection with the Old-Age Pension Act should be remunerated by the Treasury.

### Notili ation of Tuberculosis.

An interesting announcement came at the end of the business of the Sanitary Committee at Middles-brough on January 5th, when Dr. Dingle stated that he had already received 29 notifications of tuberculosis in accordance with the new order. These were from Poor-law sources, so that the number which may be notified in due course will probably be very much larger, and, being notified, it now rests with the Sanitary Committee to take what steps they may think fit to safeguard the healthy portion of the community against the unhealthy. There is bound to be some additional cost, but, as one councillor remarked, it is in the interest of the public at large that measures of some kind should be taken.

It is not surprising that the severe weather conditions recently experienced throughout the United', Kingdom should have produced an immediate effect on the death-rate, especially among the aged and the

feeble. The rates of mortality, which had been as low as 12.8 per 1,000 of the population in the large towns, rose to an average of 18.2, and in some cities to as high a figure as 24 and 30. Measured by last week's mortality, the highest annual death-rates per 1,000 living were: From all causes, 23.3 in Wigan, 23.4 in Oldham, 23.5 in Liverpool, 24.1 in Sunderland, 25.1 in Coventry, and 30.4 in Merthyr Tydfil; from measles, 2.9 in Great Yarmouth and in Rochdale, 3.0 in West Ham and in Middlesbrough, and 6.3 in Leicester; from diphtheria, 1.1 in East Ham and in Salford, 1.3 in Kings Norton and in Birkenhead, and 1.9 in Devonport; from whooping-cough, 1.1 in Swansea and 1.5 in Wolverhampton; from "fever," 1.5 in Warrington; and from diarrhœa, 1.6 in Walsall. No death from small-pox was registered in any part of the United Kingdom.

#### Infant Mortality.

At a meeting of the executive committee of the National Conference on Infant Mortality, held at the Westminster Palace Hotel on Jan. 8th, at which Councillor Anderson, of Glasgow, occupied the chair, and representatives of medical officers from all parts of the country were present, it was stated that the Prime Minister had agreed to receive a deputation to consider further resolutions which had been approved by the members of the conference.

Reports of the conference's deliberations in 1906 and 1908 are to be printed, so that local authorities in various parts of the country may be supplied with them, and the meeting approved the steps which had been taken in regard to certain clauses in the Children's

The conference tendered its thanks to the Parliamentary Committee, of which Lord Robert Cecil, the Hon. Alfred Lyttelton, and Mr. Arthur Sherwell are prominent members.

#### Nottingham City Council and Consumption.

A discussion introduced by Drs. A. Fulton and P. Boobbyer on the attitude of the municipality to the treatment of phthisis (consumption) took place at a meeting of the Nottingham Medico-Chirurgical Society last week, and it was decided by a practically unanimous vote of the members that in view of phthisis being an infective and communicable disease, dangerous to the public health, voluntary or compulsory notification of cases of it to the sanitary authority should be adopted forthwith.

### University of London.

THE following candidates passed the M.D. Examination during December, 1908:—
Branch I. (Medicine).—Henry H. Bashford, B.S.; Dorothy C. Hare, B.S.; Conwy Ll. Morgan, B.S.; John M. O'Meara, B.S.; William M. Sadler, B.S. (University Medal); William O. Sankey, B.S.; William L. Scott, B.S.; Charles A. Stidston, B.S.; Thomas M. Tibbetts; Ivy E. Woodward, B.S. (obtained the number of marks qualifying for the University Medal) University Medal).
Branch II. (Pathology).—Oskar C. Gruner (Univer-

sity Medal).

Branch IV. (Midwifery and Diseases of Women).-Frank Alcock, B.S.; David H. de Souza, B:S., D.Sc.; Robert A. Hendry, B.S. (University Medal); Ethel F. Iredell, B.A.; Clifford A. L. Mayer, B.S.; Alan Randle, B.S.

Branch V. (State Medicine).—Barbara Tchaykovsky,

B.S., B.Sc.
Branch VI. (Tropical Medicine).—Harold R. Nutt;
Oswald Marriott, B.S.

The following passed the M.S. Examination:--Walter R. Battye, B.Sc.; Athelstan J. Blaxland; Clifford A. Moore; Henry J. Nightingale (University Medal); Harold B. Whitehouse (obtained the number of marks qualifying for the University Medal).

THE Secretaries of the Conolly Norman Memorial Committee desire to remind intending subscribers that the list will be closed on January 31st. Subscriptions will be received by W. R. Dawson, M.D., Farnham House, Finglas, Co. Dublin, or J. R. O'Connell, M.A., LL.D., 34, Kildare Street, Dublin, Treasurers.

### **NOTICES TO** CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a Distinctive Signature or Institut, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule. SUBSCRIPTIONS.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January let and July lat respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messra. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messra. Sons are our special agents for Canada.

### ADVERTICEMENTS.

FOR ONE INSERTOR:—Whole Page, £5; Half Page, £2 10s.;
Quarter Page, £1 5s.; One-eighth, 12s. 6d.
The following reductions are made for a series:—Whole Page, 13
Insertions, at £3 10s.; £6 at £3 3s.; £5 insertions at £3, and
pro rata for smaller spaces.
Small announcements of Practices, Assistancies, Vacancies,
Books, &o.:—Seven lines or under (70 words), 4s. 6d. per
insertion; £6. per line beyond.

MISSING THE BOOK AND SYRDINGS.

KISSING THE BOOK AND SYPHILIS

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Dear Sir.—I hope you have read the letter of Colonel Mapleson on page 6 of last Saturday's Times and also its leader of Monday. My difficulty has always been to prove a specific case of infection from this cause. I have seen the book kissed by witnesses suffering from constitutional syphilis, and it would be very difficult to prove infection. Colonel Mapleson has clearly proved that disease may be conveyed, and it is a matter for the medical profession to follow up.

I am, Sir, yours truly,

40. Knight Street Liverpool.

40, Knight Street, Liverpool, January 9th.

Ex Uno Disce Omnes.—A course of post-graduate instruction would probably meet our correspondent's requirements. Full information respecting the post-graduate tuition in London will be found in our Students' No., published in September last.

THE PAYMENT OF MIDWIFERY FEES BY BOARDS OF GUARDIANS.

GUARDIANS.

DR. S. G. TIPPETT.—The paragraph on Nov. 18th to which you refer was founded on a statement by a responsible law journal, which, however, is not quite accurate. We have referred the matter to the central authorities, and find the only circular note issued to Guardians on the point was that of July 20th, 1908. If the District Medical Officer attends a labour when called by a midwife, he is entitled to payment should the woman be actually in receipt of relief, or should the Guardians subsequently decide that she was in a destitute condition, although no order for his attendance was given by a person qualified to make such order. The L.G.B. have decided that under the Act it is competent to pay the fee of any medical man called in on the advice of a midwife. The L.G.B. further advise Guardians to fix a definite scale of remuneration, and to exercise their powers for payment of medical men in their Unions in cases where the patient is too poor to pay the medical fee. It must be noted, however, that such action on the part of Guardians is voluntary, except in the case of District Medical Officers.

Schultzon (Barnstaple).—We have referred the query to an expert Radiographer, from whom a private note will be received by our correspondent.

A CONSCIENTIOUS BURGLAR AND HOSPITALS.

A CONSCIENTIOUS BURGLAR AND HOSPITALS.

A burgler, after breaking into the offices, last week, of the Richmond Athletic Asociation and ransacking the place, including a hospital box, left the following note:—

"As this is hospital money I am afraid to touch it. I don't wish to rob hospitals.—Yours truly, A Burglar."

### Births.

FIN.—On Jan. 9th, at Simla, Kildare, Ireland, the wife of Capt. A. W. A. Irwin, R.A.M.C., of a son cox.—On Jan. 5th, at Montrose House, Clifton, Bristol, the wife of Stuart Vernon Stock, F.B.C.S., of a daughter.

BB.—On Jan. 7th, at Kingsbridge, South Devon, the wife of William Webb, M.D., of a daughter.

### Marriages

SHEBLOCK—GALE.—On Jan. 4th, at Christ Church, Sutton, Edward Birchall Sherlock, M.D., B.Sc. (Lond.), Barrister-at-law of the Middle Temple, eldest son of Mr. and Mrs. Thomas Sherlock, of Redwood, St. Helen's, Lancs., to Phyllis Courtenay, third daughter of the Rev. Courtenay and Mrs. Gale, of Christ Church Vicarage, Sutton.

### Beaths.

BARNEWALL.—On Jan. 4th, at Ashcombe, Harrogate. Brigadesurgeon Lieut.-Colonel T. T. Barnewall, late A.M.S. and
Rife Brigade, J.P., Co., Dublin. R.I.P.

HARLAND.—On Jan. 9th, at a private nursing home in London,
in his 37th year, William Henry Harland, M.R.C.S., L.R.C.P.,
of Sandy Knap, East Cowes, I.W., late civil surgeon, 17th
Lancers, Boer War, Captain R.A.M.C., Territorials; son of
the late R. T. Harland, of Hele, Cheslire.

KILLBY.—On Jan. 9th, at 152 Highbury New Park, Thomas A
KIIIDA, M.R.C.S., L.R.C.P., aged 28.

POWER.—On Jan. 8th, at 12, Stanley Place, Leamington, and
daughter of the late Charles Wake, M.D., of Warwick, in
her 93th year.

SEDDON.—On Jan. 2nd, at Yew Lodge, Bromley, Kent, Hugh
Bonvil Seddon, M.R.C.S., L.R.C.P., aged 42, son of the late
John Pollard Seddon, F.R.I.B.A.

WHISHAW.—On Dec. 10th, at Willowburn, Queensland, Australia,
auddenly, the result of an accident, Reginald Robert
Whishaw, B.A., M.B.Cantab, F.R.C.S.Eng., aged 46.

"A distinct advance on Easton's Syrup."

BYNIN' AMARA is an analogue of Easton's Syrup, in which the sugar is replaced by an active Malt Extract. This affords a far better vehicle than syrup, as it is actively digestive and nutritious, and there is not the likelihood of the sugar crystallizing out, and carrying down in the crystal the alkaloid principle.

As a digestive tonic, the efore, 'BYNIN' AMARA is not only safer to take than Easton's Syrup, but is of greater value both in aiding and strengthening the powers of assimilation.

It has been found very effective in neuralgia and similar nerve troubles.

### COMPOSITION.-

Quinine Phosphate			1	grains
Iron Phosphate			2	,,
Nux Vomica Alkaloids e	equal to	Strychnin	ne 1	,,
Bynin, Liquid Malt .			1	ounce.

Dose for Adults-One dessert to one table-spoonful, suitably diluted.

A Sample Bottle will be sent free to Medical Men, on request.

## ALLEN & HANBURYS Ltd.,

37, LOMBARD STREET, LONDON, E.C.

UNITED STATES: Niagara Falls, New York.

CANADA: Gerrard Street East, Toronto.

AUSTRALASIA: Bridge and Loftus Streets, Sydney. SOUTH AFRICA: Castle Street, Cape Town.

# Hemaboloids

contains Iron combined with vegetable nucleo-proteids, closely approximating the natural foodform, reinforced by Peptones, Bone Marrow Extract and Nuclein.

It is in palatable, stable, non-irritating solution, does not constipate, and can be absorbed and assimilated by the most delicate stomach.

One tablespoonful contains the Iron equivalent of 20 Minims Tr. Ferri Chlor. Is indicated in all non-febrile Anemias, Adynamia after fevers, Brights Disease, Diabetes, Chronic Bronchitis and Emphysema, Cardiac disease, Neuralgias, Protracted Convalescence, etc.

DOSE: One tablespoonful 3 or 4 times per day.

Furnished in
12 oz. bottles
5½ oz. bottles

# LISTERINE

### The standard American antiseptic for internal and external use

Awarded Gold Medal (Highest Award) Lewis & Clark Centennial Exposition, Portland, 1905; Awarded Gold Medal (Highest Award) Louisiana Purchase Exposition, St. Louis, 1904; Awarded Bronze Medal (Highest Award), Exposition Universelle de 1900, Paris.

The word Listerine assures to the Medical Profession a non-poisonous antiseptic of well proven efficacy; uniform and definite in preparation, and having a wide field of usefulness.

Listerine represents the maximum of antiseptic strength in the relation that it is the least harmful to the human organism in the quantity required to produce the desired result; as such, it is generally accepted as the standard antiseptic preparation for general use, especially for those purposes where a poisonous or corrosive disinfectant can not be used with safety. It has won the confidence of medical men by reason of the standard of excellence (both as regards antiseptic strength and pharmaceutical elegance), which has been so strictly observed in its manufacture during the many years it has been at their command.

The success of Listerine is based upon merit, i.e., the best advertisement of Listerine is Listerine.

# LAMBERT PHARMACAL COMPANY,

ST. LOUIS, U.S.A.

In combating serious illness, it is doubly important to be assured that the patient is supplied with genuine Listerine, as the substitutes sometimes offered by the trade are generally of undetermined antiseptic strength, and too often worthless for the purposes for which they are required.

### Notes and Comments.

The to comment on the Report of the Inebriates' Act Home Office Committee on the Report. Inebriates' Act, in spite of the fact that it was issued only a few

Inebriates' Act, in spite of the fact that it was issued only a few going to press. The importance of hours before going to press. the recommendations contained therein is great, and we revert to the subject again to-day in a second leader. Temperance reform is still in a transition state, and medical men, who probably see more of the havoc wrought by alcohol than any other class of the community, will watch the evolution of legislative control with especial interest. The question is surrounded with doubts and difficulties, but it hardly requires the sanguine views of a confirmed optimist to inspire one with the firm and assured confidence that they will sooner or later be overcome. The day has long gone by when it could be seriously argued that to attempt to control the chronic drunkard would be to interfere unduly with the liberty of the subject. The fact of the matter appears to be that the inebriate requires control in the interests both of himself and of other folk just as much as does the lunatic. Our compulsory powers of dealing with the early stages of insanity are notably defective. It is often not until the general paralytic has committed some criminal act that his career of violence or of spendthrift dissi-pation is brought to an end. By that time his fortune has in many cases been flung to the four winds of heaven, and his relatives are deprived of their legitimate expectations.

The Parallel of Insanity.

THE need of control of insanity, especially in the early stages of general paralysis, is only too evident. It is not a whit less necessary in the case of early inebriety. The craying for

of early inebriety. The craving for strong drink, indeed, so far as that goes, is in many symptomatic of a weak moral control, and in its later stages, when organic changes have taken place, it becomes to all practical intents a kind of insanity. From a scientific point of view, it therefore seems that there is a good deal of ground for applying compulsorily a similar degree of restraint to the lunatic and to the confirmed drunkard. The case of Jane Cakebread, with her hundreds of convictions for drunkenness, is often quoted as illustrating the futility of punishment in reforming an offender of that kind. No one, however, who has read the narrative of Mr. Holmes, the police court missionary, can doubt for a moment the in-sanity of that poor woman. The Departmental Committee has taken a strong attitude. When mild measures have failed, they advise the Draconian method of indefinite detention, just as in the case of lunatics, only that every three years there is to be a sort of revision or right of appeal in each individual

case. It need hardly be remarked that such a course would require most stringent safeguards against abuse by relatives or others who might wish to apply such powers to their own selfish ends. In any case, public opinion may be trusted to determine to what extent inebriety shall be controlled in the interests of the community. Clearly something more is wanted than our present happy-go-lucky methods.

Notification of Cancer.

Notification is in the air, and many good people seem to consider that the way to scotch an infectious disease is to notify it, as though the shame of publicity would cause the

offender to obtrude itself less boldly. It is, alas! difficult to say of any disease compulsorily notifiable that it has diminished, either as the result of the notification or the measures following thereupon, but, no doubt, notification supplies interesting material for statistical study. At a recent meeting of the Malmesbury Board of Guardians, a letter was read from the neighbouring Board of Mere, asking the former to join them in applying to the Local Government Board to order cancer to be scheduled as a disease for notification under the Infectious Diseases Notification Act, and, after discussion, the Malmesbury Board decided unanimously to support their brethren in the request. While commending this zeal for hygienic measures in bodies not constituted for public health purposes, we are puzzled to understand how cancer, in the present dubious state of its pathology, could be legally regarded as a dangerous infectious disease, and, still more so, how notification would allay its progress. Doubtless, in days to come, when society is organised on ultra-Teutonic lines, we may find every case of nasal catarrh notified as being infectious, but at present the proposal to notify cancer seems rather prema-

Bermondsey Bath Water. An interesting experiment has been carried out by the Bermondsey Borough Council. Finding that water for their public baths cost high, they conceived the idea of using the

same bath water over and over again; but, let us hasten to add, after a process of purification had been gone through. The "washed water," as it is called, has been analysed both chemically and bacteriologically, and is declared to be above the average of waters supplied to baths generally. Dr. Eyre, the bacteriologist, declared the filtered water resembled the water of a new-filled bath, although it had been in the bath ten months, and Dr. Brown, the medical officer of health, says, in his opinion, the water chemically shows a great improvement over that previously used, and he considers the

system has come up to all expectations. The charge for water has fallen from £243 per annum to £5 17s., and, even with all the expenses of the new system, the cost only amounts to £174 18s. 4d. Now all this may be so, and it is good to save money and to advance the science of public bathing at the same time. But the £70 a year saved is purchased at the cost of sentiment, to which mankind is prone, and to which, in this case, we are rather apt to incline ourselves. It may be comforting to know the "washed water" is the latest triumph of science, and that its bacteria per c.c. are low as compared with the Thames or the Lea, but it is not so reassuring to the swimmer who gets a "mouthful" suddenly to realise that 2,657 Bermondsey lads have already bathed in that same water.

Catch 'em Alive.

WE have before referred to the odd notion possessed by a certain sect of amateur pathologists that acute diseases are safety-valves which prevent communities becoming the prey

of chronic ones. A letter contributed to the Daily Express of the 13th inst. seems to express this view with so much naïveté as to be worth reproducing entire:-

Measles.

To the Editor of the Express.

Sir,—Measles! What is it? Scarlet fever!
What is it? Infectious! Then how does the first child get it? May I astonish your readers by saying that these things instead of being calculations. ing that these things, instead of being calamities, are signs of vitality? Why, it would be well for England if half her sons were down with fever Why have we almost no fevers? to-day. have chronic diseases taken their places? These are the questions for patriots to answer. Will someone try to explain these difficulties?

J. P. SANDLANDS.

Brigstock, Thrapston.

The interest of lucubrations of this type lies in the fact that-in medicine, at any rate-there is no selfevident or palpable absurdity which does not find a serious coterie to support or believe in it. The idea of this grotesque letter seems to be the same as that which still widely prevails among the poor, namely, that if a rash is cured the disease is "driven in."

### LEADING ARTICLES.

THE REPORT OF THE COMMITTEE ON THE INEBRIATES' ACTS.

[SECOND NOTICE.]

In our last issue we gave a summary of the above Report, which was made public on the evening before we went to press. More leisurely consideration shows that no point of importance was omitted in that summary, but certain features of that important document appear to us to demand treatment at greater length than was possible at so short a notice. The first of these is the definition. The definition of habitual drunkard in the Habitual Drunkards' Act, 1879. is as follows:-" Habitual drunkard means a person who, not being amenable to any jurisdiction in lunacy, is, notwithstanding, by reason of habitual intemperate drinking of intoxicating liquor, at times dangerous to himself or herself or to others, or incapable of managing himself or herself and his or her affairs." The number of

flaws that have been found in this definition, and the ingenuity that has been expended in extricating habitual drunkards from its meshes, are surprising. The most ingenious of these objections lies in the strict meaning attached to the word "habitual." It has been gravely held that even if a man is an habitual drunkard, and commits an offence while drunk, the magistrate cannot sentence him because the offence may be the consequence, not of his habit of drinking, but of the particular act of drunkenness that he had indulged in at the time! It has also been said that an habitually drunken prostitute cannot be brought within the definition since her drunkenness rather assists than hinders her in the management of her "affairs"! Happily, these particular monstrosities of legal wisdom will be abolished if the definition recommended by the Committee is accepted. The definition runs:-"An inebriate is a person who habitually takes or uses any intoxicating thing or things, and while under the influence of such thing or things, or in consequence of the effects thereof is (a) dangerous to himself or others, or (b) a cause of harm or serious annoyance to his family or others, or (c) incapable of managing himself or his affairs, or of ordinary proper conduct." This definition includes as inebriates not only habitual drunkards, but habitual drug-takers, and is so far a great advance on the previous one. It avoids the first of the defects that we have recited, but in other directions we think it opens the door too wide. "Serious annoyance" is a vague term unknown to the law, and will scarcely pass the scrutiny of the Government draughtsman; while "ordinary proper conduct" is equally vague, and is already covered by the expression "managing himself and his affairs," if this last is properly understood and interpreted. The provision of "guardianship" is a novelty in legislation, and seems well adapted to meet the case of inebriates who cannot be persuaded toadopt the more serious course of placing themselves in a retreat. The guardian is to be empowered (a) to prescribe a place of residence for the inebriate; (b) to deprive the inebriate of intoxicants, and prevent him from obtaining them; (c) to require the inebriate to submit to the control of nurses or attendants; (d) to warn sellers of drink and drugs not to supply the inebriate: supply after warning to be an offence against the Act. Guardianship may be voluntarily submitted to or compulsorily imposed, the provisions in the latter case being slightly more stringent than in the former. The Committeeendorse the opinion of two previous Committees. on the subject, that "great and widespread. distress" is caused by inebriates who do not commit offences and therefore cannot be dealt with compulsorily under the present law. The Committee are convinced that power to deal with such inebriates is urgently needed; they have failed to find satisfactory reasons against the constitution of such powers, and they point out very justly, that the alternative to interfering

with the liberty of the inebriate is permitting the inebriate to interfere with the liberty of other people. It is now thirty-six years since provisions of this character were first recommended as urgent. We trust that no sentimental and misplaced tenderness for the liberty of the drunken subject will be allowed to stand in the way of his being prevented from interfering with the liberty of his sober fellows. Much consideration is given to the question of finance. The Committee says in plain terms that the expenditure of the Lancashire, Yorkshire, and London County Councils upon Inebriate Reformatories is unjustifiable and a waste of public money, and that "the mere fact that a person has become an inebriate should not of itself entitle him to be maintained under conditions altogether superior to those to which he has been accustomed." The cost of provision ought not, in the opinion of the Committee, to exceed £150 per bed, nor ought the maintenance rate to exceed 11s. 4d. per week. It is time, indeed, that an authoritative voice was raised against the profligate expenditure of public money by Local Authorities. It is on the score of economy, largely, that the Committee recommends the transfer of Reformatories to the State. but it gives with great cogency many other reasons.

#### DEATH CERTIFICATION BY MIDWIVES.

THE Departmental Committee of the Home Office, lately appointed to inquire into the question of Coroners' powers, might well ponder a case which occurred at Lincoln last week, and consider whether it and similar occurrences do not come within its reference. In the instance under notice a child was certified by a midwife and declared by a nurse, neither of whom was present at the birth, to be still-born, and in due course burial took place. Suspicion being aroused, an exhumation order was obtained from the Home Office, and medical examination showed that the child had breathed, though it was impossible to say that it had had a complete separate existence; and, moreover, that the child had failed to live through neglect at, or immediately after, birth. The Coroner, Mr. Trotter, remarked—as well he might—on the defects in the law with regard to the burial of still-born children, and expressed astonishment that, when infantile mortality is so much spoken of and deplored, those in power take no steps to amend the present faulty state of things. He proceeded to say that he could not conceive of anything easier than for people who wished to hush up the circumstances of the birth of a child who died shortly after being born, than to have the child buried on information of the sort which was given in this case, no qualified or responsible person being called in to advise as to whether the child had been born alive or not. These very proper remarks emphasise, as unfortunately those of too few coroners do emphasise, a scandal of enormous magnitude. Every medical man knows the fatal facility with which a newly-born child may be done to death and buried as still-born. All that is necessary is that no medical man shall be about the place to testify to seeing the child alive. Now, though the

doctor should be anything but a common informer, he is, by the exigencies of his position, the protector of the newly-born infant against the machinations of interested parties, be they parents or neighbours: and it is the natural result of a law which encourages the poor to do without medical assistance at their confinements, that those vicious parents who wish to murder their offspring should seek to find venal accomplices in the class to which they belong. That still-births should be unrecognised by the burial laws is equally scandalous. No child asserted to be still-born should be buried with out a medical certificate, and, if no doctor was present at the birth, a post-mortem examination of the body should be made as a matter of course. Another unsatisfactory feature is the frequent absence, as in the Lincoln case, of any attempt to encourage life, by artificial respiration or otherwise, in a newly-born child who may be an unwelcome intruder into the family. A medical man attending a confinement feels it his duty as much to resuscitate an apparently-dead child as to preserve the mother's own life; but with the abrogation or supersession of the medical attendant, the duty of doing the utmost for such an infant speedily fails to be recognised. In the particular case of which we are speaking, the Coroner, at the jury's suggestion, censured the two women, telling them they would be "lucky" if they escaped punishment for what they had done, and the Chief Constable has since taken proceedings against both. Such proceedings, however, after all, are only technical, and the fringe of the question only is touched. The parents who connive at the suffocation of the new-born, or neglect to provide proper facilities for their preservation at birth, are the parties whom a well-framed law would gather into its meshes. Such parents, for instance, as those who allow a child to be born when the mother is seated at stool or on the chamber, and make no effort to save the infant's life. However poor and ignorant people are, they know that infants born under such circumstances will not survive unless released and placed in warm and favourable surroundings, and it is prima facie evidence of infanticide for a child to be allowed to perish under such conditions. Had the Children's Act of last session devoted itself less to juvenile smoking and more to crimes of this nature, its usefulness might have been even greater than

#### CURRENT TOPICS.

An Alpine Tragedy.

On January 13th yet another name was added to the long list of Englishmen whose lives have been lost in the fascinating but fatal pastime of Alpine climbing. In this instance we regret to say that the victim was a young medical man who had already achieved a considerable amount of distinction on the threshold of his career. Mr. J. Evan Spicer set out with his brother Gerald from Lenzerheide in a westerly direction, and they were overtaken by a violent snowstorm which drove them down the steep Domleschg slope. As they did not return, a search party went out and found Gerald in a terribly exhausted condition. He reported that his brother had been swept away by an avalanche,

and was lying at the bottom of a gorge. Lenzerheide is a small health resort about eleven miles from Corbe, on the road to St. Moritz. Mr. H. Evan Spicer was educated at Clifton and at Trinity College, Cambridge. He was M.A., M.B., and B.Sc. of Cambridge (1903), and was medically educated at the London Hospital, where he held various posts, including that of Medical Registrar. The son of Mr. Evan Spicer, formerly chairman, and now Alderman of the London County Council, he carried on the family traditions by identifying himself with Free Church philanthropic work. At the time of his death he was only thirty-three years of age. His premature death once again raises the question whether the game of this dangerous mountaineering, so to speak, is worth the candle. What recompense is there for this unceasing toll of the flower of our manhood?

#### The Dangers of Pasteurisation.

In our "Weekly Summary," recently (December 30th, 1908), we briefly referred to an important investigation into the bactericidal properties of milk made by Evans and Cope, of Philadelphia. As the points raised are of considerable practical importance, we return to them here. Briefly, Evans and Cope showed that even moderate heating of milk destroys or impairs the bactericidal properties which raw milk possesses in a considerable degree. If pasteurised or sterilised milk, therefore, should become contaminated, it furnishes a much better medium for the growth of organisms than ordinary untreated milk. At the present time, many milkpurveyors have learnt that "pasteurisation" is a word to conjure with, and they inform the public that they sell nothing but pasteurised milk. If we had any assurance that the milk was efficiently protected from contamination after undergoing the pasteurising process, it would be all right. But in many cases the milk is exposed to obvious sources of contamination, such as street dust, dirty hands, or dirty vessels. The net result, under such circumstances, is that, while the pasteurisation may give protection against tuberculosis, it considerably increases the consumer's exposure to various staphylococal and bacillary infections, including such diseases as scarlatina, diphtheria, and typhoid fever.

#### Fleas and Plague in the Old Testament.

SIR HAVELOCK CHARLES contributed recently to a contemporary an ingenious speculation concerning an incident recorded in the Book of Samuel, which has given rise to much discussion on the part of commentators. It will be remembered that when, in the warfare between the Israelites and the Philistines, the ark of God fell into the hands of the latter, it was followed in its travels by "a very great destruction," the men of the cities of the Philistines where the ark rested being smitten with "emerods in their secret parts." Eventually the ark was restored to Israel, only to cause a worse destruction, fifty thousand and three score and ten among those who pried into it being smitten. It is recorded also that mice marred the land of the Philistines at that period, and they must have been supposed by the Philistines to have some relation to the prevailing epidemic, since images, not only of emerods, but of mice, were made to allay the anger of God. Sir Havelock Charles suggests that in the story we have an account of an epidemic of plague. The ark, he says, during its stay in the temple of Dagon, infested, like all Eastern temples, with rats, became infected by plague-laden fleas, to which its covering of badger-skins gave safe harbour. During its subsequent travels, even till it came to the prying Israelites of Beth-shemesh, it distributed plague. When the ark became safe from further inquisitive meddling, its power of propagating disease disappeared. The suggestion is an interesting and ingenious one, though we are scarcely surprised that the high Church dignitary, to whom Sir Havelock Charles first made it, did not receive it as it was meant.

#### A Medical Hero.

THE medical profession has its heroes, although it has not yet its "V.C." We are glad to remind our readers of the brave act of one of our Austrian brethren. The feat may, perhaps, best be narrated in the terse words of the special correspondent of the Pall Mall Gasette, whose telegram from Vienna was published in that journal on January 7th, as follows: - "By the death of Dr. Alfred Kuehne, Vienna has lost a great medical hero. Some winters ago, during a heavy snowstorm, a southern railway express ran into a sleigh at a grade crossing. The locomotive was brought to a standstill after running over the sleigh driver and crushing both his legs. Unconscious from the shock and loss of blood, the man lay under the engine, and it was impossible to extricate him. Dr. Kuehne crawled under the locomotive, and by the flickering light of torches amputated both legs, bound up the great arteries, and sewed together the wounds. To do this he lay three hours on his stomach in the snow, with the heated engine im-mediately over him. When at last the mutilated man was released from his position he was taken to the general hospital. The famous Professor Billroth declared Kuehne's work was a great deed of heroism and surgery, and his name would never be forgotten in the annals of Austrian medicine."

#### Noblesse Oblige and Medical Fees.

In the City of London Court, recently, a medical man brought a successful action against the holder of a Portuguese title. The circumstances of the case illustrate in a remarkable way the attitude of many persons with regard to the discharge of liabilities contracted through engaging the services of medical practitioners. A claim for the modest sum of £23 7s. was made against the "Baron" for attendance upon himself and a lady. It was shown in evidence that the defendant held six hundred shares in an Argentine company, and had an actual bank balance of £363. Judge Lumley Smith expressed an opinion that it would be better for the plaintiff to accept £5 per month—on what grounds it is exceedingly difficult to imagine. Why should the Court go out of its way to shield a man whose means had been shown to be ample, and whose own personal defence appears to have been conspicuous by its absence? The plaintiff very properly insisted upon the whole amount being paid. The learned judge pointed out that the sum being over £20, he was master of the situation, and the defendant "must make terms with the enemy." The last elegant phrase appears to be consistent with the familiar attitude of clients and courts when medical men pluck up courage enough to demand payment of their just dues. In the end the "Baron" was ordered to pay the whole sum, with costs, and an intimation was made that his bank balance was liable to attachment.

#### The Scotch Oath.

A FAIRLY wide-spread movement seems to be taking place to replace the time-honoured absurdity of kissing the book by the Scotch form of oath, by which the witness merely raises his hand and swears to tell the truth, the whole truth, and nothing but the truth. Several High Court judges have started the new term by a determined effort to make witnesses swear in this fashion, and magistrates and coroners are following suit. It is but the other day that witnesses were snubbed and brow-beaten by judicial authorities when they wished to follow this procedure, and we may take comfort in the fact that it is to the efforts and example of medical men that the happy change is due. The habit of kissing the book, however picturesque a survival of the Middle Ages, is about as barbarous a practice as most of the methods current in those piping times, and when but one book was provided for each court, and used month after month by countless swarms of witnesses of every shade of society, the opportunities for infection were manifold. Many cleanly-minded people kissed their own thumb instead of the book -a practice severely condemned in a medical man by Judge Bacon only last week-and the wise ones only made a pretence of inosculating the dusty tome at all; if, however, the Scotch oath is adopted universally these subterfuges will no longer be necessary. We congratulate those legal dignitaries who are sufficiently awake to the requirements of modern hygiene to endeavour to persuade people to adopt the impressive and dignified form of oath used in Scotland, and we hope the stupid and dirty old custom will soon be left to rust with broad-swords. thumb-screws, and powdered wigs, in the mouldy caverns of oblivion.

On Thursday, the 21st instant, the Conjoint Scotch and Irish Committees will hold a meeting at 4 p.m., at the Hotel Cecil to discuss the monopoly at present bestowed upon the London colleges in most of the larger hospital appointments in London and in many larger hospital appointments in London and in many of the provincial institutions. In the evening a dinner will be held at the Hotel Cecil, when several prominent representatives of the Scotch and Irish colleges will be present. Tickets (7s. 6d. each, without wine) can be obtained of the hon. secs., Dr. Hobbs-Crampton, Myddelton Square, E.C., or Dr. Parsons, 126, Fulham Road, S.W.

#### PERSONAL.

Mr. G. N. Biggs, F.R.C.S., has been appointed Aural Surgeon to the Evelina Hospital for Sick Children.

An International Hygienic Exhibition is being organised at Rio de Janeiro this year in connection with the Latin American Congress in that city. The Exhibition will be open from August 1st until September 30th.

THE LORD PRESIDENT OF THE COUNCIL has appointed Francis E. Fremantle, Esq., M.B., F.R.C.S., M.R.C.P., Medical Officer of Health for the County of Hertford, to be a member of the Committee appointed to consider the working of the Midwives

DR. CHARLES BURLAND, M.D., F.R.G.S., Board of Trade Medical Inspector for the Western District of Scotland, has been transferred to the Liverpool district, where he will be associated with Dr. J. R. Stocker.

THE Surrey County Council has appointed Mr. Fdward Hinks, Public Analyst for the County, in succession to the late Sir Thomas Stevenson, M.D., to whom he was senior assistant for seven years.

WE understand that Surgeon-General Bomford, C.I.E., M.D., Director-General of the Indian Medical Service, intends retiring before the expiration of his term of office next December. Surgeon-General Bomford has just been created a Knight Commander of the Ladies Empire. of the Indian Empire.

DR. EDWIN RAYNER, senior member of the honorary medical staff of the Stockport Infirmary, has resigned that position in consequence of the pressure of other duties. Dr. Rayner has been connected with the honorary medical staff of the Infirmary since 1875, and the Board, to mark a warm appreciation of his services, have appointed him Consulting Surgeon to the Infirmary and a Vice-President.

SEVERAL English women doctors are doing good work among the victims of the great earthquake. In Rome itself Dr. Ruth Bensusan is superintending the work of procuring supplies for the wounded refugees. She is a member of the English Relief Committee. Dr. Taylor, with whom is an English nurse, is working hard in Calabria. Dr. Caroline Matthews has left the Tiber in a ship specially chartered by the English Committee to carry food, clothes, and medical necessities to Calabria.

On the Legion of Honour list for January 1st is the name of Louis Bazy, a House Surgeon in the Paris name or Louis Bazy, a House Surgeon in the Paris hospitals. The decoration has been conferred on him by the President of the Republic personally for gallantry in the operating-room. He was assisting in an operation on a patient suffering from empyema, when a drop of pus splashed and entered his eye. He said nothing, and continued his duties until the operation was successfully concluded. Only then did he have his eye treated, but it was too late, and violent infection set in. Acute inflammation followed, lasting six months, and causing great pain. At length the eye had to be removed.

MR. JOHN CHARLES LANE, of Moseley, Worcestershire, solicitor, bequeathed £100 each to the Birmingham General Hospital, the Queen's Hospital, Birmingham, the Birmingham Blind Asylum, the Birmingham Deaf and Dumb Institute, the Birmingham Ear and Throat Hospital, the Birmingham Eye Hospital, the Birmingham Children's Hospital, the Jaffray Hospital, the Birmingham Skin and Lock Hospital, the Middlemore Homes, and the Moseley Park Hospital. After family bequests have been satisfied, the ultimate residue of his property, which has been valued at £31,280, is to be divided equally between the above charitable institutions, which will apparently share between them a further £12,000.

A PROVINCIAL sessional meeting of the Royal Sanitary Institute will be held in Manchester on Friday, Institute will be held in Manchester on Friday, January 22nd, including, at 2.30 p.m., a visit to the new Manchester Royal Infirmary, and at 7 p.m. a discussion in the Municipal School of Technology on the Manchester Royal Infirmary from the Hygienic, Sanitary, and Æsthetic Points of View, which will be opened by Mr. Edwin T. Hall, Vice-President R.I.B.A., followed by Mr. John Brooke, F.R.I.B.A. (architects of the infirmary). The chair will be taken by Mr. H. D. Searles Wood, F.R.I.B.A.

### A CLINICAL LECTURE

ON

#### CEREBRAL ABSCESS.

By WILLIAM TAYLOR, M.B. Dub. Univ., F.R.C.S.I.,

Surgeon to the Meath Hospital and Co. Dublin Infirmary, &c.

HAVING recently had some cases of intracranial complications of old standing suppurative disease of the middle ear under my care in the hospital, and having accidentally come across this patient, on whom I operated in 1903, I thought it would not be inappropriate for us to consider the subject of cerebral abscess this morning. Let me now briefly read to you the notes of this case, and remind you of the case we had in the adjoining ward some three weeks ago, and then we shall be in a position to review the subject generally.

J. R., æt. 17, was admitted under my care into the Meath Hospital on August 3rd, 1903, from Cork Street Fever Hospital, into which institution he was taken two days before on account of severe headache and vomiting. He had had a discharge from both ears for a number of years, and had attended as an out-patient at one of the eye and ear hospitals for some time. A few days before admission into Cork Street Fever Hospital he began to complain of severe headache, which was chiefly confined to the left side. He vomited almost continuously for two days, especially if he moved his head from one side to the other. The evening before going into hospital he had a shivering fit. On admission into Cork Street Hospital his temperature was found to be 104°, and the pulse varied from 90 to 100. He looked very ill, and complained much of the intensity of the pain in his head.

Dr. T. L. Sandes, who was doing temporary duty as Assistant Medical Officer, examined the patient, with the following result: There seemed to be no discharge from the left ear, but it was full of granulation tissue; there was a profuse discharge from the right ear. Tenderness was not complained of on percussion or firm pressure over either side of the head. The fundus of the eye was examined on each side. The fundus showed early evidences of "choked disc." but the right fundus was normal. The boy spoke distinctly enough, but, it was thought, somewhat slowly, as if his cerebration was dull. There was no evidence of paralysis or paresis of any cranial nerve, or of any of the limbs. He was deaf, but stated that he had been a little deaf for a long time.

Dr. Sandes considered the case one of cerebral abscess, and accordingly communicated with me. I saw the patient about 11.30 p.m., and found his condition much the same as already detailed, with this exception—that he no longer complained of the headache, but he seemed more or less delirious, and spoke rather incoherently, and pronounced some of his words indistinctly. The left pupil was more dilated than the right, and contracted very sluggishly to light. The temperature was still about 104°, and the pulse about 90. Considering the severity of the headache, and the persistent high temperature and acuteness of the case, I was more disposed to look upon the case as one of septic meningitis, but determined to operate upon the patient next morning as soon as he could be removed to the Meath Hospital, where the facilities for performing an operation such as would be required were much better. Next morning he was in a semi-unconscious state. Temperature was still high; pulse had fallen to 80. The left pupil was widely dilated and did not react to light; the right pupil was only moderately dilated.

He was immediately trephined over the left temporosphenoidal region. This site was selected: first, because at that time it was considered to be the commonest situation of intracranial abscess of otitic origin; secondly, on account of the indistinct pronunciation of some of his words; and, lastly, on account of the dilatation of the left pupil. These

points, however, I will draw your attention to later on. A disc of bone was removed directly above the external auditory meatus, and the opening quickly enlarged in every direction, until it measured roughly a inches antero-posteriorly, and 11 inches vertically. The dura mater bulged into the wound; it was very tense, and did not pulsate. A flap of dura was then reflected upwards, when the brain protruded well beyond the opening into the skull. On palpating the protruding brain to see whether I could detect a softened spot, my finger actually opened into the abscess cavity, so superficial was the abscess and so ready was it to rupture. I assume it was only prevented from rupturing into the membranes by the force with which the increased intracerebral pressure applied the surface of the temporo-sphenoidal lobe to the surrounding membranes. The finger was passed into the abscess cavity to explore it. The cavity was very gently and cautiously syringed with saline solution, and some sloughing brain tissue removed. Two drainage tubes were introduced side by side into the abscess cavity, and brought out through an opening in the centre of the dural flap, which was adjusted with catgut sutures, as well as the protruding brain admitted, to the cut margins around the bone opening. The scalp was then brought up, and a hole cut near its: base for the drainage tubes to pass through. The edges of the flap were adjusted by silkworm gut sutures, and the tubes fastened to the edges of the opening in the scalp by similar sutures. The tubes were cut so that they protruded merely 1 of an inch beyond the scalp. The usual dressings were applied, and the patient returned to bed. It was noticed that directly the abscess was evacuated the pulse increased in rapidity to 140 to the minute.

The subsequent course of the case was uneventful. Morphine had to be given rather freely for 24 hours after operation on account of the irritability of the patient. His temperature became normal in a couple of days, and his pulse gradually quieted down to the normal. Six weeks subsequently a radical mastoid operation was performed, and he has since then remained perfectly well. His hearing is much better, and beyond the fact that you can feel the defect in the skull from which the bone has been removed, there is no evidence to suggest that he had ever had any intracranial complication from his suppurative

ctitis media.

A few weeks ago you may remember we had another somewhat similar case, which was sent here from Cork Street Fever Hospital. The history was different in a few respects, viz., his otitis media dated back to the age of 7 years—he was then about 30 years of age—the otitis was double, too, and discharged freely for a number of years. It then dried up and remained well for some 14 years, when it returned without cause, so far as the patient knew. He was admitted into Cork Street Fever Hospital for enteric fever, and it was during convalescence his troubles began. For a couple of days he had very severe vomiting, distinctly cerebral in character—that is, it was apparently purposeless and unaccompanied by nausea, it was independent of food, and seemed to be produced by any sudden movement of the head or change of position of the head from one side to the other. He complained of headache; for a short time one day he had loss of memory—he could not remember where he lived, or where he was, or for what reason he came into hospital, nor even his name; this lapse of memory was only temporary. His temperature was sub-normal, and his pulse varied from 70 to 84 in the minute.

sionless, or it may assume, as Macewen puts it, "a meaningless smile with which the features are not lit—

it is too mechanical."

Choked disc may be present; it usually is, and is generally most marked on the affected side. The patient med to answer rather slowly. There was no tenderes on pressure nor pain complained of anywhere on percussion over the skull. He quickly became conscious, but from the clear history of loss of mory, severe cerebral vomiting and headache, which re sent with the patient from Cork Street Fever Hosal, I trephined over the left temporo-sphenoidal are and evacuated a very large abscess. That situate and was again selected for the following reasons: the terminal stage is characterised by the evidences of the abscess either into the ventricles or on to the surface into the membranes, or by the evidences of spreading cedema. Rupture is recognised by a convulsion, profound coma with widely dilated pupils, livid face, and hurried or stertorous respirations. The pulse runs up from 40 or 60 to 120. 140.

by a convulsion, profound coma with widely dilated pupils, livid face, and hurried or stertorous respirations. The pulse runs up from 40 or 60 to 120, 140, or 160. The temperature bounds up from normal or sub-normal to 104°, 105°, or more, and death takes place within a few minutes to a few hours. Spreading cedema is indicated by gradual onset of coma, dilatation of the pupils, quickening of the pulse, with loss of its tension, while the breathing not infrequently assumes the Cheyne-Stokes type, and the temperature rises; finally, death takes place from respiratory paralysis.

Unfortunately, one does not generally see cases of cerebral abscesses so typically illustrating the phenomena of the three stages just described. The patient is generally found in the second stage, and, as a rule, well on in it, and bordering upon the third or terminal stage.

Ballance classifies the symptoms of brain abscess as follows:—

(1) Those due to the presence of deep-seated pus independent of its locality, such as the febrile state, with perhaps a rigor and vomiting.

(2) Those due to increase of tension within the skull,

(2) Those due to increase of tension within the skull, such as purposeless vomiting, slow, high-tension pulse, choked disc, and torpor.

(3) Those due to irritation or suppression of function of particular parts of the central nervous system, such as epilepsy, anæsthesia, paralysis, perversion or loss of one or other of the special senses.

The phenomena of Ballance's third group are, of

The phenomena of Ballance's third group are, of course, the localising phenomena indicating the area of brain in which the abscess is situated, phenomena which might just as well be produced by a tumour.

As regards the site of brain abscesses, traumatic abscesses will be found directly underneath the situation of the injury. Those from the frontal sinuses, for example, will be found most frequently in the frontal lobes, while those taking their origin from infective otitis media will be found either in the temporo-sphenoidal lobe or in the cerebellum. It has generally been stated that the commonest site for abscess secondary to suppurative otitis media is the temporo-sphenoidal lobe, but I am inclined to doubt the correctness of the statement. Certainly, in children, at all events, I have seen cerebellar abscess more frequently, and the statistics of St. Thomas's and the Great Ormond Street Hospitals, quoted by Mr. Ballance in his book on "Some Points in the Surgery of the Brain," go to show that abscess of aural origin is more frequent in the cerebellum than in the temporo-sphenoidal lobe.

As regards the localising evidences of an abscess in the temporo-sphenoidal lobe, I may tell you at once that there may be none whatever, and this is more especially the case with abscesses situated in the right temporo-sphenoidal lobe, which is the most "silent" area of the brain.

We may have the cortical centre for hearing partly or entirely involved, producing tinnitus, hyperacusia, or absolute deafness of the opposite healthy ear. Provided the other ear is known to be healthy, this may be of importance.

be of importance.

The cortical centres for taste and smell, which are situated in the lower and anterior extremity of the temporal lobe, forming the uncinate gyrus, may be effected.

Sensory aphasia often occurs in abscess of the left temporo-sphenoidal lobe; the auditory word centre and visual word centre are those chiefly involved.

A large abscess in the temporo-sphenoidal lobe may cause paralysis of the opposite side of the body, which

There was neither paresis nor paralysis. The fundi of both eyes were normal, although examined twice at antervals of some days. He spoke clearly and distinctly, but again, when I saw him, I thought he pronounced some words indistinctly, and I thought he seemed to answer rather slowly. There was no tenderseemed to answer rather slowly. There was no tenderness on pressure nor pain complained of anywhere on firm percussion over the skull. He quickly became unconscious, but from the clear history of loss of memory, severe cerebral vomiting and headache, which were sent with the patient from Cork Street Fever Hospital, I trephined over the left temporo-sphenoidal lobe and evacuated a very large abscess. That situation was again selected for the following reasons: first, there was some indistinctness in the way the patient pronounced some words; secondly, there was a clear history of loss of memory for words, showing some involvement affecting the speech mechanism. The pulse became greatly accelerated directly the abscess was evacuated, but, unfortunately, the patient never recovered consciousness. His temperature rose quickly and steadily to 105.4°; his pulse kept fast; the pupils remained widely dilated; and he died comatose some 24 hours after the abscess was opened. The post-mortem showed the temporo-sphenoidal lobe on the left side to have been extensively destroyed by a large abscess which still contained a small amount of pus, though the drainage tube was well within the abscess cavity. The most noticeable feature in the case was the absence of any sign of choked disc in the presence of so large an abscess. As regards the ætiology of cerebral abscesses, the

As regards the etiology of cerebral abscesses, the commonest causes are chronic suppurative disease of the middle ear and trauma; then comes pyæmia, following septic processes in the lungs, such as gangrene, abscess in the lung, chronic empyema, etc.

The most important group comprises those which occur as the result of a more or less direct extension of septic processes from suppurative disease of the middle ear, mastoid cells, and the sphenoidal and frontal sinuses. It is thus obvious that infection may reach the brain either by direct inoculation; by metastasis through the blood stream (pyæmia); by direct extension of the suppurative process from extracranial cavities; and by inoculation through infected blood-vessels (emissory and diploic veins) which connect with the extracranial or extradural suppuration.

Symptoms and Signs.—It is customary in this country to follow Macewen in describing the clinical course of a cerebral abscess. He describes three distinct stages:—(1) The initiatory or irritative stage. (2) The stage of fully-formed abscess, sometimes termed by him the latent stage. (3) The terminal stage.

The features characteristic of the first stage are: Severe headache, referred chiefly to the ear and temporal region of the affected side, but radiating in different directions; a rigor, which varies from a mere feeling of chilliness to a rigor so severe that it may be mistaken by the uninitiated for a convulsion; vomiting, cerebral in type; a rise in temperature, and quickness of the pulse. There is, in addition, generally the history of the antecedent condition—usually a history of long-standing discharge from the ear, with possibly the statement that the discharge ceased directly before these severe symptoms began. This stage lasts a variable time, from ten or twelve hours to two or three days.

Second stage: Latent stage, or that of fully-formed abscess, is characterised by a fall in the temperature to normal or sub-normal; a slow pulse—70, 60, or even 40 to the minute; dulling of the intellect; slow cerebration—he answers questions slowly and distinctly, but he seems to require a much longer time to understand the question put to him, as well as to formulate the reply; sometimes you are almost about to repeat the question, thinking he did not hear it, when out comes the answer, uttered slowly and generally correctly. The vomiting of the first stage generally ceases, and the headache subsides, or, at all events, it is no longer complained of. There is no actual paralysis unless the abscess is situated about the motor areas, but there seems an inability to apply the strength, and the patient seems incapable of any sustained mental effort. Constipation is obstinate, and there may be retention of urine. The face is expres-

may be of cortical or capsular type. The paralysis due to pressure of the abscess upon the motor fibres as they are closely grouped together while passing through the internal capsule is that of a complete contralateral hemiplegia, developing quickly in the order: leg, arm, face; and it is generally associated, as might be expected, with hemianæsthesia. The paralysis arising from pressure of the increasing abscess upon the motor fibres as they pass down from the different motor areas of the cortex, is a slow, progressive paralysis, gradually extending from the face to the arm, and lastly the leg, but generally without anæsthesia.

The third nerve on the same side may be paralysed in the case of temporo-sphenoidal abscess. Ballance lays great stress on this fact. The paralysis is rarely lays great stress on this fact. The pararysis is factly complete, but, he says, "a stable pupil on the side of the suspected abscess clinches the diagnosis."

Lastly, there may be paralysis of the "naming entre"—that is, there may be a lesion or pressure upon that centre which presides over the nervous mechanism by which the ideas of objects are correlated with their This centre seems to be located in the left temporo-sphenoidal lobe. It was probably this centre which was affected in the last case you saw here, where which was alected in the last case you saw here, where the patient could not remember where he lived nor even his own name for a while. The condition may be termed "aphemia." A considerable area of even the left temporo-sphenoidal lobe seems to be "silent"; thus a small abscess may exist there without producing any localising phenomena. It is then simply by obtaining the clinical history of a discharge from the ear, and excluding cerebellar abscess, the localising evidences of which I will now mention, that you will be enabled to treat the case satisfactorily.

An abscess in the cerebellum, while small, may give rise to few symptoms, and the patient may be able to go about; but, as it increases in size, serious symptoms develop.

Vertigo is marked, and he is unable to co-ordinate his movements. He reels from side to side if he attempts to walk; even when sitting up in bed the patient cannot be got to sit quite upright; he tends to fall, as a rule, towards the side opposite to that in which the abscess is situated. There is frequent yawning of a mechanical character, and the head is retracted. The vomiting of the first stage may persist,

especially on movement.

The respiration is greatly embarrassed, may be of the Cheyne-Stokes type, and may suddenly become arrested, due to direct pressure upon the respiratory centre. This sudden arrest of respiration has not in-frequently taken place while the anæsthetic was being administered for the purpose of opening the abscess. Should such an accident occur, artificial respiration should be maintained, the skull quickly opened, and the abscess evacuated. The removal of the pressure from the respiratory centre by the evacuation of the abscess allows it to resume its function again. Several cases of this nature, in which patients' lives have been saved, are on record. In cerebellar abscess, paresis of the external rectus muscle on the same side is one of the commonest isolated signs of cranial nerve ir volvement

Skew deviation of the eyes is a not uncommon sign, one eye being turned upwards and outwards or up-wards and inwards, the other being turned downwards and outwards

Nystagmus may also be detected.

A cerebellar abscess may cause a paresis of the limbs on the same side as the lesion; the face is not involved, and the paresis is not accompanied by rigidity; the muscles are flaccid. The lesion tends to involve the larger movements rather than the finer, and is not associated with ankle-clonus.

The knee-jerk on the side of the lesion is often exaggerated, but it may equally be diminished. It is not my intention to go into the question of localisation of cerebral abscesses in other situations. The traumatic is easily localised by the injury, and the temporosphenoidal and cerebellar abscesses are the only other abscesses frequently met with. In any case, it is a question of knowing the functions of different areas of the brain. Tenderness on percussion over the site of the abscess should always be sought for. It should be remembered that these abscesses of otitic origin are

not infrequently complicated with septic thrombosis of the sigmoid or lateral sinus, and, if so, you will invariably find that the sigmoid sinus thrombosis phenomena predominate over the cerebral, and thus mask them. The general cerebral phenomena only assert themselves when the septic sinus condition has been relieved by operation.

General Diagnosis. - Abscess of the brain must be dis-Cervical Diagnosis.—Abscess of the brain must be distinguished from inflammation of the membranes. Cervical rigidity and Kernig's sign are more suggestive of meningitis than abscess, while a lumbar puncture will show whether the cerebro-spinal fluid contains an increased number of leucocytes, a condition always present in meningitis and absent in cerebral abscess,

unless it is complicated with meningitis.

Sigmoid or lateral sinus thrombosis is characterised by the peculiarly spiky course of the temperature. The condition of the pulse is that of severe systemic sensis. It is quick-110 to 140-and small. There are multiple rigors. There is tenderness over the mastoid, and perhaps along the internal jugular vein, and there may be cedema over the mastoid process and pulmonary phenomena.

Tumour of the brain is hardly likely to lead to diffi-ilty in diagnosis from abscess. The antecedent culty in diagnosis from abscess. history is the important thing.

Sometimes in otitis media one finds symptoms produced by a reflex disturbance through the trigeminal nerve, which may closely resemble intracranial extension of the disease. There is no rise of temperature, but great tenderness, headache, nausea, and even vomiting may occur. The tenderness is, however, superficial, and conforms with the sensory distribution of the trigeminal nerve. Even the hair cannot be touched without producing discomfort. Cushing states that he has seen several cases of that sort recover without operation, and he attributes the phenomena to a mild degree of dural involvement. Cushing also states that another still more common complication due to an acute serous meningitis (not of bacterial origin, at all events, so far as is known) may closely simulate abscess. In such cases a lumbar puncture or a decompressive craniectomy, with evacuation of the fluid, is sufficient to cure. He therefore advises that in any exploratory operation for abscess, if a super-abundance of clear fluid is disclosed, it is not wise to be too persistent in the search for pus.

Prognosis.—Without operation the prognosis is hopelessly bad, and, even after operation in the most experienced hands, the mortality must be at least 50 per cent. The treatment consists in the evacuation of the abscess the moment the diagnosis is made. Delay of a few hours may mean the rupture of the abscess or the development of a spreading cedema which will terminate fatally, in spite of the evacuation of the abscess, as witness the case operated upon recently.

There are two methods of procedure. Otologists-recommend starting with the cause of the trouble. They open the mastoid antrum, throw this cavity and the attic of the ear into one, and then follow wherever the disease leads, upwards into the middle fossa and temporo-sphenoidal lobe, or backwards, removing the mastoid cells and exposing the sigmoid sinus, and thus explore the cerebellum. For this method of procedure there is much to be said. Still, in these days of specialism, general surgeons have not much opportunity of becoming familiar with the performance of radical mastoid operations, and they will probably obtain better results if they attack the brain trouble directly, and leave the ear trouble to be dealt with later on Macewen, at all events, favours the latter method, and so, indeed, does Cushing. Ballance, however, favours the mastoid route, but then Ballance made that operation more or less of a speciality. I have done both, and in any case in which the symptoms are at all urgent I prefer to go direct for the brain.

To explore the temporo-sphenoidal lobe, the simplest and most efficient method is that of exploration by the muscle-splitting temporal route of Harvey-Cushing. It can be done in a few minutes; the squamous portion of the temporal bone is thin and easily cut through. One can thus explore intracranially the roof of the tympanum, the dura over it, and, if necessary, the temporo-sphenoidal lobe, and in case an abscess is found therein, it can be most efficiently drained at its most dependent part. After exposing the brain, it can be explored by a hollow needle with a blunt end and one or more side openings, or by a long, narrow-bladed metacarpal knife. Not infrequently in cases of chronic cerebral abscesses the wall becomes so thick and firm that nothing but a sharp knife will penetrate it. I have seen such a wall to a chronic cerebral abscess. When pus is found the abscess should be freely incised here, as elsewhere, and in cutting you should avoid the sulci as far as possible, so as to avoid the risk of hæmorrhage. Provide for free drainage. Some men always irrigate the cavity, but it should be done with the utmost caution and gentleness, due precaution being taken to prevent any increased tension within the cavity, or any diffusion of the septic process to the surrounding areas. Drainage is difficult on account of the fact that the cerebral substance about the edges of the incision in the brain become edematous, and tends to occlude the opening, and thus cause retention of the discharges. I generally use two drainage tubes, each about \(\frac{1}{2}\) in in diameter, placed side by side. These are brought out through an opening in the centre of the dural flap, and project about \(\frac{1}{16}\) to \(\frac{1}{2}\) of an inch beyond the edge of the scalp, to which they are fastened by a couple of silkwormgut sutures. Dressings are then applied, and the patient put into bed with the affected side of the head down, so as to facilitate drainage.

A cerebellar abscess, if urgent, can quickly be explored as follows: Place the trephine so that its anterior border is just behind the posterior border of the mastoid process and its upper border just below Reid's base line. After opening the dura, pass the exploring needle or knife in a direction forwards, upwards, and inwards, through the cerebellum towards the posterior surface of the petrous portion of the temporal bone. It should be remembered that if the abscess is situated towards the anterior and inner aspect of the cerebellar hemisphere, the needle or knife must be passed inwards, forwards, and upwards for as much as 2 inches from the surface before pus will

be found.

Having once opened a cerebral abscess, the important point to pay attention to subsequently is to see that drainage is satisfactory. Recurrence of headache, vemitting, and drowsiness, with the development of a hernia cerebri, are evidences of imperfect drainage, and the re-accumulation of pus, which must be evacuated at once by passing a knife or sinus forceps along the sinus. Then introduce a larger tube.

Never allow your patient to leave the hospital or pass from your care until the wound is soundly healed.

At the present time, when lumbar puncture is so fashionable, but nevertheless so valuable, both diagnostically and therapeutically, you should always be cautious in employing this procedure in the presence of cerebral or cerebellar abscesses. Had this procedure been employed in either of the two cases referred to to-day, the altered conditions of tension would unquestionably have led to rupture of the abscess into the membranes. If lumbar puncture is employed as a diagnostic measure, be careful, therefore, to withdraw but a very small amount of fluid.

Note.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Arthur Whiting. M.D.Edin., M.R.C.P.Lond., Physician to the Prince of Wales's General Hospital, Assistant Physician to the Mount Vernon Hospital for Consumption and other Diseases of the Chest; Lecturer in, and Dean of, the North-Bast London Post-Graduate College. Subject: "The Peroneal Type of Muscular Atrophy."

A PUBLIC subscription list has been opened in the Isle of Wight with the object of providing a county public memorial of the late Dr. J. Groves, J.P., who was for many years Medical Officer of the rural district of the Isle of Wight, and was actively associated with various public institutions. Dr. Groves was President of the Society of Medical Officers of Health during session 1903-4.

#### ORIGINAL PAPERS.

# THE SALICYLATES IN RHEUMATIC AFFECTIONS.

BY RALPH STOCKMAN, M.D., F.R.C.P.E.,

Professor of Materia Medica in the University of Glasgow; Physician to the Western Infirmery, Glasgow.

It is now generally conceded that acute rheumatism is a specific fever. The prominent part played by the joint affections, owing to the pain and helplessness of which they are the cause, have in the past somewhat obscured the proper conception of it as a general blood infection with local manifestations tending to implicate specially certain tissues and organs, but the high temperature, the leucocytosis, the anæmia, the arthritis, the endo- and pericarditis, and the tendency to natural cure, stamp it as a typical fever with a close general resemblance to many other diseases of the same class. Its duration varies from a few days to three to six weeks. One attack does not confer immunity, but rather predisposes to others. This suggests continued infection such as is seen often in rheumatoid arthritis and tubercle, and sometimes in gonorrhœal rheumatism, where, after periods of latency, the infected person suffers from acute exacerbations. It is probable that many cases of rheumatic infection are very slight; there may be only sore throat with a trifling rise of temperature and some malaise, or it may take the form of a so-called "chill," with no typical symptoms whatever, and rapidly aborting.

In considering ordinary well-marked cases, such as are sent into hospital with the diagnosis "rheumatic fever," it seems to me that two

types may be distinguished clinically. In the first the temperature ranges from 102° F. to 104° F., there is much constitutional disturbance, usually several joints are very swollen and painful, there is abundant sour-smelling acid perspiration, and as the inflammation in one joint subsides, others become implicated in turn. These cases are very susceptible to salicylate treatment; they are of shorter duration, show less tendency to relapse, and are less liable to be followed by

sequelæ than the others. In the second type the joints are not so prominently affected, but the fibrous tissues about the chest, the lumbar aponeurosis, the fascia lata, the periarticular tissues, the tendon-sheaths, and the subcutaneous fibrous tissue are tender and painful, sour-smelling sweats are absent, the temperature is not so high,

and salicylate treatment is not nearly so effective. These cases linger on, relapses are more apt to occur, and sequelæ such as chronic fibrositis and

perineuritis are much more common.

In the present indeterminate state of our knowledge regarding the specific organism of rheumatic fever it is impossible to say whether these are two different diseases, or merely differing clinical types of the same disease. Cases of mild pyæmia, of osteo-myelitis, of gonorrhœal arthritis, and of rheumatoid arthritis, are often, in their early stages at least, very difficult to differentiate from cases of acute rheumatism, and as yet we have no absolute diagnostic such as is afforded by the bacillus of tubercle, or the agglutination test in enteric fever. We have to rely for a diagnosis entirely on clinical experience. In most cases of acute rheumatism it has been found impossible to cultivate an organism from

the blood or joint fluid. It is true that in a few cases diplococci, streptococci, and staphylococci, have been obtained from the blood during life. but bacteriologists are not in agreement as to whether these constitute the primary or merely a secondary infection. Post-mortem, similar organisms are often obtainable from the synovial membranes, the heart valves, and the meninges. Achalme has isolated an anærobic bacillus which he regards as the specific cause, while it has even been suggested that the organism is a protozoon. The reason for this last view is interesting, although possibly not of much weight, namely, that hitherto only protozoon diseases as malaria, syphilis and sleeping sickness, have shown themselves susceptible to drug treatment, while bacteria, in the living body at least, have practically defied specific drugs.

Many competent observers (Singer, Sahli) still hold the view that acute rheumatism is merely a mild pyæmia, and it is quite possible that many cases diagnosed and treated as rheumatic are really pyæmic, but I think we may safely conclude that there is a special non-pyogenic organism, and that it is the cause of a train of distinctive symptoms which go to make up the clinical picture of

acute rheumatism.

From its first introduction into practice it has been almost universally recognised that salicylic acid and compounds from which it can be formed in the body have a powerful and quite specific action in this disease. Some practitioners go so far as to base their diagnosis of a case on its reaction to salicylic treatment. But cases of acute rheumatism react in very different degrees. In some its action is prompt and effective like the crisis in pneumonia, in others it may be slightly slower, or very much slower, and in certain cases the temperature and general condition remain far from satisfactory. Relapses may even occur while the patient is taking the drug. If, however, there is absolutely no beneficial effect, I think we may conclude that the disease is not rheumatic. In some cases the unsatisfactory results of salicylic treatment are undoubtedly due to the dose being too small. When it is increased each time, or a substantial addition such as 40 gr. given once daily, matters often mend at once, and the temperature falls. Apart from this, however, those cases where the fibrous tissues are chiefly affected never do so well as those in which the joints are mainly involved. This is susceptible of more than one explanation. The two conditions may be due to different, although allied, organisms, which are not equally influenced by salicylic acid. There is nothing impossible in this, as in typhoid and paratyphoid fevers, and in human and bovine tuberculosis we have much the same clinical symptoms produced by differing microbes. Another possible explanation is that organisms lodged in the fibrous tissues are more protected, or under more favourable circumstances for continued existence, than those in the blood and joints, and hence offer more resistance to the drug. Certain cases of pericardtis yield very readily to salicylates, while in others they have practically no effect, and in my mind there is no doubt that here we are dealing with different organisms. I do not refer to cases of pneumococcic or tubercular pericarditis, but to those which are clinically and customarily reckoned as rheumatic.

Once the microbic origin of acute rheumatism and its complications and the specific action on

them of salicylic acid are admitted, the logical outcome is to treat cases early and with large doses, in order to kill off the organisms while they are still in the blood and joints, and before they have established themselves in the fibrous tissues from which they are dislodged with very much more difficulty. I believe that "chills" of rheumatic origin are rapidly cured in this way, while those which happen to be of influenzal or other origin derive no benefit from salicylates. The doses need to be large and frequently repeated, partly because salicylic acid is so rapidly excreted, and partly because it is converted into the inert salicyluric acid. There is no danger in pushing it as regards the circulation, which it affects very slightly, its main poisonous action being exerted on the nervous system and respiration. The action of salicylic acid in acute rheumatism is undoubtedly specific. It is of little or no therapeutical value in other febrile diseases, and it exerts no action on the healthy man from which one could infer its action in rheumatic fever.

But besides clinical evidence, the chemical evidence points conclusively in the same direction. Phenol (C<sub>6</sub> H<sub>5</sub>, OH) has no action on rheumatism, but benzoic acid (C<sub>6</sub> H<sub>6</sub>, COOH), a direct derivative, has a very marked effect only inferior to salicylic acid ( $C_6$   $H_4$ , COOH, OH) or ortho-oxybenzoic acid, as it is called chemically. Its isomers meta- and para-oxybenzoic acids are practically inert, although possessed of the same chemical constitution, and only differing in the position occupied in the molecule by the hydroxyl group (OH). No explanation has ever been forthcoming for the cause of this remarkable difference in action. The cresotinic acids (C<sub>6</sub> H<sub>3</sub>, COOH. OH, CH<sub>3</sub>) are all active, the carboxyl and hydroxyl group being in the same relative positions as in salicylic acid. Salicin, saligenin, acetyl-salicylic acid, methyl salicylate, and several other sub-stances are active only because salicylic acid is formed from them in the body, while populin (benzoyl-salicin) methyl-salicylic acid, and dimethyl-salicylic acid, from which no salicylic acid is formed in the body, are inert. Phtalic (C<sub>6</sub> H<sub>4</sub>, COOH, COOH) and toluic (C<sub>6</sub> H<sub>4</sub>, COOH, CH<sub>3</sub>) acids are also quite inactive against rheumatism. So far, no chemical or pharma-cological explanation has been forthcoming of the specific effect of salicylic and benzoic acids in acute rheumatism, while so many closely allied substances are inert.

#### SYPHILITIC FACIAL PARALYSIS.

By Prof. G. MILIAN, M.D.,

Chef de Clinique de la Faculté à l'hôpital St. Louis.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

As long ago as 1830 Dr. Bell described facial paralysis of syphilitic origin, but only in a vague, general way, and it is comparatively recently that its real history has been elucidated.

It is customary to classify cases of syphilitic facial paralysis as early and late, and I shall adhere to this plan, although it is not altogether appropriate.

Facial paralysis is one of the most frequent secondary paralytic manifestations, and it is also one of the earliest, as was shown by Dieulafoy, who, in fifteen cases in which the onset was well marked, met with it once in the seventh month, once in the sixth, once in the fourth, four times in the third, seven times in the second, and once in the first month. It will be seen, then, that it is commonest between the second and the third month of an attack

of syphilis, and it could hardly supervene much earlier than that.

The pathogenesis of this paralysis is much debated. By some it is ascribed to a basic meningitis; by others to gummatous periosteitis of the petrous bone pressing on the nerve, while Fournier, among others, believes it to be a peripheral toxi-infective neuritis.

However this may be, we must certainly discard the idea of a cerebral origin, since the superior facial nerve is attacked just in the same way as the inferior; then, too, the notes of the cases nowhere comprise signs pointing to any cerebral implication, neither hemiplegia nor ictus.

Headache is generally absent, and, as Louste remarks, the cranial pain has nothing to do with the facial paralysis, but is in reality a neuralgic pain in the skin of the cheek and mastoid region, indicative of neuritis rather than an encephalic origin.

There is obviously pressure on the nerve in some instances, but in the majority of cases the cause must be sought, not in any such pressure, but in

toxi-infection.

The rapid disappearance of the muscle and the palpebral reflexes, itself an unquestionable sign of neuritis, by the earliness of its supervention in syphilitic facial paralysis, shows that the nerve is profoundly attacked in its structure, much more rapidly, in fact, than in ordinary compression paralyses.

We may also add the protracted duration of the lesions, because "in presence of osteitic compression the effect of the treatment is usually very prompt. In true lesions of the nerve the duration is much longer if we consider neuritis and polyneuritis occurring in toxic infective diseases similar to syphilis.

Symptoms.—Early syphilitic facial paralysis does not differ in any essential particular from ordinary peripheral facial paralysis a frigore. It may be bilateral.

When it supervenes it attacks forthwith all the branches of the facial nerve, the superior as well as the inferior, so that it presents the appearance of peripheral facial paralysis. It may be accompanied or not by painful sensations.

As a rule the pain is felt, not in the cranium, but over one side of the face, especially in the genio-temporal, auricular, and mastoid regions. It does not correspond to the distribution of the trigeminal, but to that of the facial nerve, and it is generally most acute in the auricular and mastoid regions. The pain presents a characteristic feature—vis., that it occurs in the form of paroxysmal attacks, recurring several times in the course of the twenty-four hours, especially at night, when it may render sleep impossible.

Dieulafoy explains the production of the pain in the area of a motor nerve by assuming the participation of the intermediate nerve of Wrisberg, which is considered by anatomists, on account of its central relations with the nucleus of the glosso-pharyngeal, as the equivalent of a posterior spinal root-in other words, it constitutes the posterior root of the facial nerve, the ganglion whereof is the geniculate ganglion. The paralytic phenomena do not present any distinctive feature. The paralysed side of the forehead is motionless and does not wrinkle, the eye cannot be closed, and remains wide open, or half open, when that on the opposite side is shut; the cheek is flaccid and the zygomatic fold is effaced. The lip is motionless and the labial commissure is deviated to the healthy side; the tip of the nose is also turned to the healthy side, owing to muscular dragging. When the patient opens his mouth to speak and tries to contract his features, the symptoms become much more obvious, owing to the contrast between the immobility of the paralysed side and the contraction of the normal side.

We must also mention epiphora, due to paralysis of Horner's muscle. When there is a lesion of the intra-petrous portion of the facial nerve, in addition to the paralytic phenomena, we get disturbance of taste over one-half of the tongue on the paralysed side, due to paralysis of the chorda tympani, and of hearing from paralysis of the nerves innervating the chain of ossicles.

This form usually runs a mild course, and is soon recovered from. In three or four weeks of mer-curial treatment the symptoms clear up and no trace of the affection remains.

Late Facial Paralysis.—Late facial paralysis is of less frequent occurrence, and it may supervene at any time between the third and the tenth or twentieth year. It is not, like early facial paralysis, due to neuritis, but to pressure on the nerve, either in the Fallopian canal from periosteitis of the petrous bone, or to a patch of sclero-gummatous meningitis at the base of the brain.

The symptomatology of this form is the same as the other, except in cases which are due to paralysis consequent upon meningeal compression. In the latter event it is very rare for the patch of meningitis to be strictly localised to the point of emergence of the facial nerve. The neighbouring nerves are also involved, as a rule, especially the auditory, external ocular, and the trigeminal nerves. When this is the case, lumbar puncture almost in-variably reveals the existence of marked lymphocytosis of the cerebral spinal fluid.

The prognosis in late facial paralysis depends entirely on the date at which the treatment is instituted. If it be commenced immediately on the appearance of the earliest paralytic symptoms, complete recovery may safely be foretold, for the gummatous infiltration has a good chance of clearing up before the nerve has time to become degenerated as the result of the pressure. If, on the contrary, the diagnosis is not made at once, and treatment be deferred, the nerve may undergo complete destruction, in which case the paralysis is, of course, irremediable.

Diagnosis.—The diagnosis of facial paralysis is easy enough. The important point is to ascertain the ætiological factor, and this is often overlooked.

In early paralysis, the presence of other secondary symptoms cannot fail to direct the practitioner's attention to the syphilitic origin of the paralysis, but three or four years after the chancre the facial paralysis may be the only manifestation of syphilitic infection.

When, in a case of facial paralysis, we are unable to elicit any history of sore throat, otitis, fracture of the petrous bone, or recent acute infection, especially zona, we must discuss the possibility of a syphilitic origin, and only admit the a frigore hypothesis as a last resort, should inquiry fail to discover anything pointing to the probability of syphilis. Even so, it may be well to prescribe a course of mercurial treatment. The occurrence of the correlation of the correlation of the correlation of the correlation of the correlation. other paralytic lesions of the cranial nerves along with the facial paralysis is an almost certain indication of a syphilitic influence.

One mistake that should be avoided-and it is easy enough to avoid-is to mistake hemiplegia with facial paralysis for a peripheral facial paralysis, that is to say, for a paralysis of the nerve trunk.

You are all aware that hemiplegia is of common occurrence in the syphilitic, quite at the onset, during the first few months of the infection, just as in the later periods. We must be careful not to take simple facial paralysis for commencing hemiplegia, for that would be a grave error, since hemiplegia implies permanent damage to the patient, whereas facial paralysis ends in recovery, or, in any case, leaves but a moderate degree of infirmity.

The differential diagnosis is easy to make, since the facial paralysis in hemiplegia only involves the distribution of the inferior facial nerve, or, at any rate, is more marked therein. The frontal muscles and the orbicularis are intact, or but slightly affected, and can perform all the movements, provided these be performed in conjunction with the muscles of the opposite side. The non-involvement of the superior facial, therefore, is here an element in the diagnosis. But we must also steer clear of the opposite mistake of mistaking a bulbar hemiplegia for facial paralysis of the peripheral type. You are aware that lesions of the medulla are manifested by total facial paralysis of the muscles on the same side as the bulbar lesion, and paralysis of the upper and lower limbs on the opposite side. We must, therefore, never omit to examine the limbs in presence of facial paralysis, whatever the history may be. This will enable us to avoid overlooking existing hemiplegia, or to assert its existence when it is absent.

# THE MANGOSTEEN TREATMENT OF DYSENTERY.

By MICHAEL AMBROSE, F.R.C.P. AND S.I., Newcastle West.

THE dysentery to which I refer throughout this article is the amœbic or tropical form of the disease; and as I am about to describe a drug treatment of it, practically, if not entirely unknown to the profession, I propose doing so by giving the history of four typical cases taken from clinical notes of some few hundred recorded during epidemics that prevailed in the Far East (Ceylon, Singapore, Penang, Shanghai, etc.), during the late summer and early autumn of last year (1907).

I treated the cases that came under my care for the first few months, or up to the end of August, with the ordinary methods so familiar to us all. Fresh ipecacuanha root, given with its usual auxiliaries, sulphate of sodium or of magnesium in repeated drachm doses, mercury, bismuth, and even quinine, per rectum, as recommended by Osler. However, all these treatments, combined with suitable dietary and rest, proved to be of little avail, most of the non-fatal cases lapsing with time into the chronic form of the disease. I consulted with several medical practitioners at the places which I have named and found them using various cures, one physician even prescribing fresh strawberries, as recommended by certain Continental authorities; but all confessed their inability to cope with the epidemic—people dying by the score after two or three days of hopeless diarrhæa, even in Shanghai, where sanitation tends to the best under the direction of its able Medical Officer of Health, Dr. Arthur Stanley.

On August 24th we took on board at Colombo a Mr. W—, æt. 32, who was travelling round the world in order to recuperate from neurasthenia caused by overwork. He told me that, unfortunately, since his arrival to the tropics in June, he had been subject to diarrhæa of blood and mucus, alternating with constipation, which former had been examined when he contracted the disease in Ceylon and the "amæba dysenteriæ" isolated. When he came under my care he was having what he called one of his "bad weeks" (i.e., constant diarrhæa); so I tried freshly-powdered ipecacuanha, without any good effect, when the mag sulphate treatment had failed.

On arrival at Penang on the morning of the 29th, the patient was in a very weak condition; and during a conversation with the chief officer of the R.M.S. Delta (Mr. Louis Pickney), he informed me that the rind of that excellent fruit, the mangosteen, was used

by natives as a cure for severe endemic diarrhœa. He also told me the way to prepare it for use, and that by adding a quantity of Chinese sugar, it would allay the primary tormina caused by the drug. I got some mangosteen rinds, roasted and powdered and mixed the powder with Chinese sugar in the proportion by weight of two of the former to one of the latter; a powder to which I will again refer to as pulv. mangosteen co. I gave a drachm dose of this compound powder at 9 o'clock p.m. (29th), with similar doses every fourth hour, and the motions though still containing blood and mucus, decreased from an average of 20 to 12 for the following twelve hours; encouraged by this result, I administered drachm doses every third hour until 10 o'clock p.m. (30th), at which hour the patient passed a "formed stool," free from blood and mucus, the first stool that he had passed free from same since the end of June (so I was informed by a male nurse who travelled with patient since he left England); I kept him on drachm doses thrice daily and twice a night until September 3rd, when all dysenteric symptoms ceased and I failed to find the amœba in the stools. On leaving the ship, on arrival at Shanghai next day (4th) he was, according to his own words, "cured." I followed up the case for the following "cured." I followed up the case for the following three weeks, and although he ceased taking the mangosteen toward the end of the second week the dysentery did not recur. Since then I was informed that he returned to England for Christmas, but was not again troubled with the complaint.

The next chronic case is that of an Indian native, Mhd. Mawale, æt. 30, fireman, R.M.S. Delta. This was a very chronic case, extending over nine months, with some dozen intervals of from two to four days; yet the symptoms were never so severe as those of the European passenger. I put patient on pulv. mangosteen co. I dr. doses, ter in die, after first clearing out his bowels well with repeated drachm doses of mag. sulphate, so that the mangosteen would come in direct contact with the bowel. He gradually improved, until on the sixth day blood and mucus had left his stools. Being much worn out by the constant diarrhea I put him on suitable tonics with an occasional dose of mangosteen (pulv. mangosteen co. I dr. every second morning), and am glad to state that within a month he

was restored to perfect health.

As to the acute cases, the most striking that I can select for this article, from amongst several, is that of a Mrs. M. K., æt. 36, European, who came under my care on October 20th, having contracted the disease in Colombo, and the acute symptoms of dysentery appearing on the second day of voyage. I put her, immediately I was called to case, on pulv. mangosteen co., I dr. every second hour for the first twelve hours, with rest and suitable dietary of meat juice and diluted milk. On October 21st the stools had decreased by 25 per cent., and both tormina and tenesmus were much less; I decreased the dr. dose from every second hour to every fourth hour, during day and night, and kept patient on this until the 24th, or fourth day of disease, when the stools lost all signs of blood and mucus, and within a week I failed to find the amœba in the stools. This was amongst the quickest and most decisive cures that I have experienced from pulv. mangosteen co.

As a second acute case, let me select that of a native cook, Abdoonamen Bafaty, æt. 30, who came under my care on September 5th, with very acute symptoms. I put him on suitable dietary and pulv. mangosteen co., I dr. every second hour, as in latter case, for the first twelve hours; when the stools lost a quantity of the accompanying blood and mucus, although they rather increased in number. Towards the end of the second day the tormina and stools decreased, and the latter continued to do so, while administering dr. doses every fourth hour of the compound powder, until on the tenth day of malady blood and mucus had disappeared from the stools; and a search for the amæba proved negative. I put the patient on suitable tonic (mist. ferri.) and occasional doses of the mangosteen every other day until he returned to duty on the 24th of the

THE MEDICAL PRESS. 61

The mangosteen, which belongs to the same family as the apple, grows on a tree named by botanists, Garcinia Mangostane, natural order, Guttiferæ. The tree came originally from Malacca, and in appearance resembles the apple tree very much. It has to be planted about nine years before it yields a crop, but when it does so there are two a year, and continues doing so until forty years of age. I gathered these facts during a visit I paid to a mangosteen orchard near Penang; when the owner, a wealthy native, told me that there was only one variety of the tree, and that the only other country it grows in besides the Federate Malay States is Jamaica, where he had exported plants to some twenty years previously. The fruit has a terra-cotta coloured rind of a quarter of an inch thickness, and of a tough, pulpy consistency, inside which there is the fruit proper, which cannot be better described than by saying it is the exact likeness of the inside of the orange, but white instead of the latter's golden yellow colour. I brought a quantity of the powdered rind to England, as the fruit does not bear such a journey, and submitted it for analysis to Park, Davis and Co., but I regret to say that owing to the time available that the result has not yet reached me from their Detroit Laboratories, U.S.A. I found on later experiments that the pulv. mangosteen is just as, if not more, satisfactory by itself as with the Chinese sugar; the addition of which latter I now regard as nothing more than a native custom and having no effect on tormina one way or the other. The doses that I recommend are up to a drachm every second hour in acute cases, and a half-drachm thrice a day usually suffices for chronic cases.

#### OPERATING THEATRES.

ROYAL FREE HOSPITAL.

COMPOUND FRACTURE OF THE SKULL.-MR. WILL. MOTT Evans operated on a man, æt. 47, who had been admitted suffering from injury to the head as the consequence of a fall in the street. The patient was quite unconscious and could not be roused. On the right side of the head was a wound some three inches in length, with contused edges, and from it was escaping a stream of blood. That part of the skull was obviously depressed below its normal level. The limbs on the right side of the body were somewhat rigid, but those on the left side were completely flaccid. The pupils were unequal, the right being contracted and the left widely dilated; they were both insensitive to light. The breathing was stertorous, and the pulse was full and strong. It was stated that the accident had happened some hour and a-half previously, and that his condition when picked up was practically identical with that at the present time. Immediate operation was decided on, but no anæsthetic was employed. Almost the whole of the head was shaved, washed and cleansed carefully. The wound was then examined: when the finger was introduced it came upon some rough edges of bone, and examina-tion increased the flow of blood. The wound was enlarged by a curved incision so as to form two flaps which were raised from the bone and the fracture was easily seen. It was found that there was a troughshaped depression, mainly longitudinal in direction, situated over the parietal eminence and in front of it. The blood was coming from the anterior part of the depression. An attempt was made to pick out one of the broken pieces of bone, but this proving difficult it was decided to trephine. An inch trephine was taken and the pointer placed on a projecting angle of un-broken bone, and a disc of bone was removed. It was then comparatively easy to take away several neigh-bouring pieces of depressed bone, and others were raised and restored to their former position. Through the opening by the removal of some portions of the bone it was possible to examine the dura mater, and it was seen that nowhere had it been perforated. The it was seen that nowhere had it been perforated. examination was especially careful along the very bottom of the depression; some portions of de-

pressed bone were especially removed from the site of the bleeding, so that the source of hæmorrhage might be examined: the blood was seen to be coming from a small vessel in the dura mater, a branch of the great middle meningeal artery. It was impossible to seize it with forceps in the ordinary manner, but by means of a fine curved needle a silk suture was passed round it and the vessel was tied. No other vessel required ligature. The whole wound was thoroughly washed out with hot normal saline solution and the edges drawn together with silk sutures. rubber drainage tube was placed near the centre of the wound, and a dressing of double cyanide gauze was applied. During the operation it was noticed that soon after the depressed bone had been removed or raised, the breathing had become less noisy and the pulse was distinctly softer when the patient was removed from the theatre.

Mr. Evans said it was obvious from even a brief examination of the man that he was suffering from compression of the brain. The stertorous breathing, the full pulse and the unequal pupils all pointed to this. Since the unconsciousness came on immediately it was probable that the increase of intracranial pressure was due to depressed bone, and not to hæmorrhage, for there is usually an interval of consciousness of some twenty minutes or more between the infliction of the injury and the development of coma when intracranial hæmorrhage is the cause of the compression. The wound in the scalp, and the depression of the vault of the skull both pointed clearly to the site of the increased pressure, but it must always be borne in mind that in some cases two lesions exist, one of which, the more obvious, is not the real cause of the symptoms of compression. In regard to the question of anæsthetic, a patient suffering from compression needs none. The incision in the scalp depends on the case: the old crucial incision is little used nowadays; it gives four flaps to be retracted, and the wound in the scalp coincides with the wound in the bone. When the scalp wound is small the best incision is semi-circular, with the wound somewhere about the middle of the flap so formed, and the base of the flap is directed downwards. This flap is easily retracted, a good view is provided of the injured part, and the incision of the scalp does not correspond with the wound in the bone. In the present case the scalp wound was too extensive to make the semi-circular flap of much use; the wound, therefore, was simply enlarged. For elevating bone it is necessary to find some opening into which the elevator can be inserted; if this cannot be done it is necessary to trephine. It is important to bear in mind that the pin of the trephine must rest on unbroken bone; if attention be not paid to this matter, the pressure needed for cutting the bone will depress still more the depressed bone, and increase of the damage to the brain may result. The question arises: Is it necessary to remove all the depressed bone, or will elevation suffice? So far as possible, it is better to elevate than to remove, for the removal of a portion of the skull leaves a permanently weakened spot. It is necessary, however, to remove sufficient to examine carefully the deeper structures. In the present case the dura mater was not torn, and therefore the risk from sepsis was much reduced. Should the removed bone be replaced? In an aseptic operation it is always desirable to replace as much bone as possible, but when, as in the present case, an extensive scalp wound accompanies the fracture, a certain amount of sepsis is sure to be present, and the risk of necrosing of separated fragments is materially increased; therefore, it is not, as a rule, desirable to replace any fragment of bone which has been completely cut off from its blood supply. Some little difficulty is sometimes experienced in stopping the hæmorrhage from wounded vessels of the dura The expedient adopted in this case, he considered, is the best, where it is not possible to seize the vessel with forceps. The chief trouble is experienced in stopping the bleeding from a meningeal vessel lying completely enclosed in a canal of the bone, as sometimes happens. In a case like this, aseptic wax may be employed, or a small piece of catgut may be

wedged into the opening. Drainage, he thought, is always desirable in cases where a wound has had an opportunity of getting septic. As to the dressing for operation cases which are from the start aseptic, he employs simple sterilised gauze, but for wounds which are septic, or may be septic, he thinks antiseptic dressings are preferable.

The patient began to recover consciousness in three or four hours. He progressed rapidly. The wound healed for the most part by first intention, the tube being removed on the second day. At the end of ten days healing was complete, and the man was allowed to get up. The weak spot in the skull measured about an inch and a-half by one inch, but no protrusion existed. He left the hospital perfectly well three weeks after the injury.

#### TRANSACTIONS OF SOCIETIES.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD JANUARY 13TH, 1909.

The President, Dr. James RITCHIE, in the Chair.

#### CASES.

Dr. George A. Gibson showed (i) a case of cerebral diplegia, with exaggeration of all the superficial and tendon reflexes, and a remarkably characteristic cross-legged gait; (2) a very typical case of acromegaly in a woman, æt. 50. There was the characteristic enlargement of the hands and feet; the lower jaw was enlarged, its angle had become obtuse, and the lower teeth projected in front of the upper ones. The superior maxillæ and the orbital sinuses were also enlarged. There appeared to be enlargement of the thymus gland, and also of the pituitary body; the latter was causing bilateral temporal hemianopsia. The patient was absolutely deaf. There had been no increase in stature; there was no enlargement of any of the hollow viscera. A peculiar point was the presence of swelling of the finger-joints and some muscular wasting of the hands, suggestive of rheumatoid arthritis.

Dr. NORMAN WALKER showed (1) a case of "grouped" comedones. The patient was a young woman, and the comedones were distributed along a diagonal line running over the front of the chest towards the left shoulder and extending down the left arm. He was unable to offer any explanation of the unique distribution. Grouped comedones were usually found in localities where some special cause—the pressure of the collar, or the wearing of a fringe—could be traced. (2) A case of primary sore on the chin of a boy. Besides the large initial lesion two smaller ones were present. (3) An unusual form of tertiary ulceration of the thigh.

Dr. LOVELL GULLAND read a paper on STONEMASON'S PHTHISIS.

He had been led to inquire into the nature of the disease in connection with the operation of the Workman's Compensation Act, the question having arisen whether stonemason's phthisis was a disease due to occupation or whether it was primarily tubercular. In Edinburgh stonemason's phthisis was very common, on account of the freestone so much used in building. It was worked in open sheds, which were very dusty. His material was derived from the statistics of the in- and out-patient departments of the Victoria Hospital for Consumption over a period of four years, during which time routine examination of the sputum for tubercle had been in operation for all cases. During that period 7 masons had been treated as out-patients, and 36 as in-patients. Of the latter, all were tuberculous, as only tuberculous patients were taken into hospital. Of the 7 out-patients, 11 were builders and 76 hewers, showing a marked preponderance among the men who worked in the dusty sheds. Two were not lung cases at all, and one was suffering from emphysema, leaving 55 with definite physical signs of lung disease. Dividing the cases according to age, 1 was under 20, 11 between 20 and 30, 21 between 30 and 40, 33 between 40 and 50, 15 between 50 and 60, and 40 over 60. The maximum incidence of the disease, therefore,

occurred much later than in ordinary pulmonary tuberculosis, which was most common between 20 and 30. Taking the age incidence in in-patients, it was found to be earlier; this was probably because only early cases were admitted. The family history of the patients compared favourably with the other cases treated at the Victoria Hospital. Dividing the cases according to the stage of the disease into mild, with signs of affection of one apex; medium, with both apices affected; and advanced, with signs of excavation; 22 were early, 29 medium, and 29 advanced. Of the in-patients, 7 were early, 3 medium, and 26 advanced. The physical signs in general were identical with those of tuberculous phthisis. The sputum was examined in 54 of the 89 out-patients, and in 37 of 36 in-patients. Tubercle bacilli were present in all the latter, and in 48 of the former; the remainder of the out-patients were either cases who attended only once, or in whom sputum was not obtainable. In considering these 89 cases of stonemason's phthisis, it must be remembered that some of the patients would have contracted tuberculosis in any case, whatever their trade had been; others contracted it late in life, in consequence of their occupation. He believed that all the cases of stonemason's lung were tuberculous.

Dr. Affleck said it was a tradition among masons

Dr. AFFLECK said it was a tradition among masons that the wearing of beard and moustache diminished

the liability to the disease.

Dr. RUSSEIL remarked on the importance of Dr. Gulland's statistics, which were he believed, the first to show exactly the frequency of tubercle bacilli in mason's phthisis.

Dr. Andrew Walker said that in Aberdeen, where granite was worked by pneumatic machinery, mason's phthisis was common.

Dr. Edwin Matthew read a paper on the

ACTION AND USES OF VASO-DILATORS IN HIGH PRESSURE.

Of the numerous medicinal substances—thyroid, benzoates, iodides, etc., beneficial in hypertension only nitrites and nitrates are vaso-dilators. These are only nitrites and nitrates are vaso-dilators. drugs in daily use; they are all powerful vaso-dilators, and their use depends on an accurate know-ledge of their action. He had made a series of comparative observations on liquor trinitrini or nitroglycerin, sodium and potassium nitrite, erythrol tetra-nitrate and mannitol hexa-nitrate. The drugs had been administered to patients with high blood pressure, a regular sphygmanometric obervation had been made in their action on blood pressure, noting the time they took to act, the fall in blood pressure produced, the time of maximum effect, the duration of maximum effect, and the time of return to normal. His results were as follows:-Liquor trinitrini, 2 to 3 minim doses. Action began in 1 minute; pressure lowered by 25-30 mm. Hg.; maximum effect in 5 minutes; duration of lowest pressure 2 minutes; return to original level in half an hour. Repeated doses caused some tolerance to be established. Sodium and potassium nitrite, 2 gr. doses. Action begins in 5 minutes; pressure falls by 32 mm. Hg; maximum action in 15 minutes; duration of lowest pressure, ½ hour; return to original level in 2 hours. Erythrol tetra-nitrate. Action begins in 6 minutes; pressure falls by 32 mm. Hg.; lowest pressure attained in 25 minutes, remains at lowest point for 2 hours; return to original level in 6 hours. Mannitol hexanitrate. Action begins in 15 minutes; pressure falls by 32 mm. Hg.; maximum fall in 100 minutes; lowest pressure acts for 21 hours; return to original level in 6 hours. Vaso-dilator drugs were not curative, but palliative, to stave off advancing hypertension, in the pre-sclerotic stage of arterio-sclerosis. Liquor trinitrini was only useful where brief and speedy action was desired. Pressure could not be permanently kept down by its use, as tolerance was quickly established, and the effect of each dose was so short. Larger doses than 2 minims might lead to unpleasant symptoms. Erythrol tetra-nitrate, given every 6 or 8 hours, was an effective means of lowering pressure. In certain cases of high pressure, however, especially chronic interstitial nephritis, vaso-dilators were useless, as they did not reduce the blood pressure.

Drs. Russell, G. A. Gibson, and Ritchie discussed Dr. Matthew's paper.
Dr. Dawson Turner gave a lantern demonstration

showing some results of

ELECTROLYTIC TREATMENT AND RONTGEN RAY DIAGNOSIS.

Among the slides shown were a number illustrating the healing action of zinc-electrolysis in cases of rodent ulcer, a method of treatment Dr. Turner considered superior to X-rays. Skiagrams showing the diagnosis of pulmonary tuberculosis, aneurysm, pneumothorax, the use of bismuth in the X-ray diagnosis of oesophageal and intestinal mischief, renal calculi, and other medical conditions were also demonstrated.

#### GLASGOW MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD FRIDAY, JANUARY 15TH, 1909.

Dr. WALKER DOWNIE in the Chair.

A SHORT paper on NYSTACHUS, AND THEORIES REGARDING ITS CAUSATION, was read by Dr. W. B. J. POLLOCK. He arranged the various kinds of nystagmus under four heads-namely, (1) congenital, (2) acquired, (3) pathological, and (4) labyrinthine. Congenital nystagmus was in most cases due to some serious defect of vision resulting from loss of transparency of the cornea or lens, or defect in the development of the optic nerve. Acquired nystagmus was usually due to some unhygienic condition of the cornea or lens, or defect in the development of the optic nerve. dition in the occupation, and is commonest in miners and paper workers. It appears to be due to locomotor exhaustion of the muscles of the eyeball. Pathological nystagmus occurs as a symptom of some other disease, such as disseminated sclerosis. Labyrinthine nystagmus is the result of irritation of the labyrinth of the ear, and has some importance in the diagnosis of laby-rinthine diseases. The various theories as to the causation of nystagmus were enumerated, and that propounded by Gowers being put forward as the most probable. Cases were shown to illustrate different varieties of nystagmus, and an interesting discussion followed, in which Dr. W. Syme and Dr. A. Gray made remarks upon labyrinthine nystagmus.

Dr. Jas. F. Gemmill gave a demonstration of the Auriculo-Ventricular bundle of his.

Sections were exhibited by the microscope and by the lantern demonstrating the presence of this interesting muscle in the healthy adult human heart, and also in the fœtal heart of a calf. This bundle of muscular fibres was traced from its passage through the fibrous septum in both directions; one passing to the ventricle walls to end there in the musculo-papillaris; the other end passing to the "Knoten" or nodal point and thence to end in the muscular walls of the auricles, some fibres being traced as far as the cardiac end of the sinus venosus. The presence of two large bloodvessels was shown in the bundle, and the presence of a large number of ganglionic nerve cells was also demonstrated, these being most numerous at the "Knoten.'

Dr. John M. Cowan showed a series of tracings of the venous pulse, illustrating different conditions of alteration in the rhythm of the cardiac wave, which may result from interference with the auriculo-ventricular bundle of His. The tracing showed alteration in the rhythm of the cardiac contractions in various different ways, and demonstrated that disease of the auriculo-ventricular bundle of His was capable of giving rise to irregularities in rhythm of the heart contraction wave, and even reversing the direction of this as in heart-block.

#### ULSTER MEDICAL SOCIETY.

MEETING HELD THURSDAY, JANUARY 14TH.

Sir William Whitla in the Chair.

Dr. R. W. LESLIE read notes and showed a case of pseudo-hypertrophic paralysis in a child, æt. 8. The case was discussed by several members.

Dr. Maguire showed a tumour removed from the axilla of a woman, æt. 60, with microscopic sections for diagnosis. The tumour was a most uncommon one, and opinions as to its nature were widely divergent. Considerable interest has been aroused in it, and specimens will be sent out of Belfast for further

expert opinions on it.
Mr. Howard Stevenson showed a child of 3, with extensive congenital lipomata, and the deformity of giant feet. The case was most interesting and curious, and drawings are to be made of it for the Society.

Mr. A. B. Mitchell read a paper on "A Method of Operating for Varicose Veins," illustrated by photographs. The paper, which will be published later, was discussed by Sir William Whitla, and Messrs. Fullerton, J. B. More, and Howard Stevenson.

Miss Crawford (Lurgan), Dr. R. L. Moore (Bangor), and Dr. Cahill (Belfast), were elected Fellows of the Society, and Dr. Flannigan (Belast) a Member.

Paris, Jan. 17th, 1909,

OBESITY IN WOMEN.

OBESITY of genital origin in women is closely allied to menstrual troubles or sterility, as all medical men since Hippocrates have remarked. A paper has been just published by Berkovitch in which he has given the conditions under which this genital obesity is observed.

Obesity is frequent in young girls at the period of puberty who are generally anæmic or chlorotic and "irregular." The obesity disappears more or less rapidly as the menses become more regular. Sometimes, instead of adipose tissue, an elastic cedema, un-influenced by the finger-print, is observed. This cedema is more particularly observed on the face in the morning; sometimes around the ankles, especially in the

Another frequent type is post-nuptial obesity, which sets in immediately after marriage, provoked, perhaps, by exhaustion of the ovaries through excessive stimulation; from the same cause obesity is very common in prostitutes, but here, however, alcoholism and the dolce far niente play an adjuvant rôle.

Maternal obesity is no less frequent during the course

of the first months of pregnancy, due, according to M. Charrin, to two or three causes—ovarian and hepatic insufficiency and a certain sluggishness of the oxida-Sometimes the adipose tissue recedes more or less after delivery, but more generally the obesity progresses after gestation, and especially after nursing.

Another well-known type of obesity in women is that observed at the close of uterine activity. Here it is due, not so much to the suppression of the menstrual flux as to the disturbance in the function of the ovaries, and in particular to their internal secretion, which controls the oxidations of the feminine organism. It is thus that, after ablation of the ovaries or surgical castration, obesity has been very frequently observed.

According to M. Berkovitch, obesity of more than half the women is due to one or other of the causes above-mentioned.

The treatment is clearly indicated: preparations of ovarian bodies, powder, or extract, which, according to M. Mace de Lepinay, have produced considerable improvement in many cases.

#### SYMPATHETIC OPHTHALMIA.

Pure sympathetic ophthalmia is caused by propaga tion to the healthy eye of septic uveitis of the diseased eve. The most favourable conditions of this infection is a penetrating wound of the ciliary body, especially when the penetration is accompanied by the presence of a foreign body. Accidental wounds

consequently take the front rank in the ætiology of sympathetic ophthalmia. In some cases, operative wounds (extraction of cataract) might be incriminated as well as perforating ulcer of the cornea, certain intraocular neoplasms, spontaneous cyclitis with phthisis of the globe as a consequence.

The treatment of this affection is simple enough, as it consists in enucleation of the eye; any other opera-tion, according to M. Velude, is absolutely illusory. Evisceration or section of the optic and ciliary nerves, as recommended by Schweigger and Wecker, are not advisable. The operation, which requires but two instruments—an écraseur and a pair of scissors—is of the simplest kind. M. Velude recommends the old practice of passing a thread through the cornea and held in the left hand. By this thread the globe is drawn forward as the muscles are being cut, rendering

unnecessary hooks or assistants.

As to the time of operating, much depends on the nature of the accident and the sensitiveness of the eye. With the modern antiseptic methods, suppressing for the most part infectious complications, an attempt should be made to preserve the organ if no foreign body be present; it should not be sacrificed, however, except where the patient is observed to suffer from repeated attacks of cyclitis. But if the eye continues to be painful, it is better prudence to remove it. Naturally, where the healthy eye suffers, through sympathy, from photophobia, ciliary injection, excessive secretion, enucleation should be performed with-out delay and the other eye treated by mercurial frictions on the forehead, the temples and the arms. Some authors recommend sub-conjunctival injections of sublimate (1-1000).

GERMANY.

Berlin, Jan. 17th, 1009

At the Medizinische Gesellschaft, Hr. Thummim reported the case of a girl, of 17, who first menstruated at the age of 15, but not again. At this period a very luxuriant beard began to develope, hair also grew on the breast and on the linea alba, the voice became deeper, but the figure remained feminine. The external genitals were distinctly feminine, the uterus was normally developed, the ovaries were plainly to be felt under an anæsthetic as small hard substances. The girl died from sepsis, commencing in a panaritium. The autopsy showed the mamme to be well developed, female genitals and a feminine pelvis. The ovaries were small and hard without any trace of ovulation. There were two brown nodules in the right supra-renal body, the left was converted into a tumour the size of a man's fist which proved to be a struma supra-renalis. The thyroid was enlarged, but the hypophyses were not. It was, therefore, a case of atrophy of the germ glands with hypertrophy of those of the vascular system. The speaker thought it would be interesting to study the relationship between the two conditions.

ACUTE OBLITERATING FIBROUS BRONCHIOLITIS.

Hr. A. Fraenkel furnished a further contribution on this subject. He reminded his hearers of his previous contributions, and observed that he had had but few followers. He had observed a total of four cases. The essentials of the affection consisted in this, that connective tissue closure of the bronchioles very quickly took place, i.e., those air vessels that were free from cartilage, that had a diameter of 0.4 to 1 mm., and which terminated in alveoli. The process was similar to that in indurative pneumonia; first there was a fluid exudation in the passages with round cells which became organised and led to closure; in indurative pneumonia, however, the process was limited to the part that was the site of pneumonic infiltration, in fibrous bronchiolitis it was the site of pneumonic infiltration, in fibrous bronchiolitis it was the site of pneumonic infiltration, in fibrous bronchiolitis it was the site of pneumonic infiltration, in fibrous bronchiolitis it was the site of pneumonic infiltration, in fibrous bronchiolitis it was the site of pneumonic infiltration, in fibrous bronchiolitis it was the site of pneumonic infiltration. diffuse, and spread over the whole lung. The alveoli became emphysematous, the emphysema developed wherever the bronchioles were stenosed, and the surface of the lung looked almost like miliary tuberculosis; covered with a large number of small nodules, in which on closer inspection a central depression was to be seen, which was wanting in miliary tuberculosis; the nodules were frequently also smaller or larger than those of that disease. The whole of the appearances was in favour of injury to the lung from respiration, and as a matter of fact in all the four cases, the patients were all young people between 20 and 30 years of age who, from their occupation, were compelled to inhale acids or dust.

On describing the preparations he spoke again of the nodules, which were not rounded, but pointed or angular in form. The process usually began in the wall of the bronchiolus, and passed thence to the alveolar passages, whilst the infundibula of the alveoli remained free, apparently because the bronchial spasm that came on, and later, the connective tissue closure of the bronchioles prevented the entrance of

Clinically, the chief feature was excessive dyspnœa, and cyanosis without any proper dulness; widespread or the lung. The absence of tubercle bacilli in the sputum, and the absolutely negative result of ophthalmoscopic examination prevented any confusion with miliary tuberculosis, in the pneumonia of influenza the dulness was more pronounced, and the sputum also contained the bacilli of influenza. In measles on the other hand there were changes in the lung that appeared to correspond with those of bronchiolitis obliterans, but they were always con centrated in some sections of the lungs, so that death did not result from the hindrance to respiration, but was due to other factors. The disease was sometimes accompanied by high fever and sometimes not, and on two occasions the speaker had diagnosed the con-

dition during life.

From what had been stated the disease was a very serious one. Treatment was powerless; only the inhalation of oxygen gave some relief, and possibly allowed a substance to take place where the exudation was still fluid. On the other hand the prophylaxis was important, and was of course to be directed to the prevention of injury to the lungs from any

industrial occupations.

Several speakers took part in the discussion, amongst them Herren v. Hansemann, J. Lazarus, and Benda.

> AUSTRIA.
> Vienna, Jan. 17th, 1909. EFFECT OF SHOCK.

BENEDIKT presented a male patient, æt. 29, to the members of the Gesellschaft, who was brought to him on November 20th, after hearing sad news, with his head and hip drawn to the right. When the eyes were closed the deformity was increased, and he was in danger of falling towards this side. The patient seemed to have the greatest difficulty to retain his equilibrium owing to his inability to carry the body towards the The right leg was highly adynamic and hyperæsthetic in touch, pain and temperature. This condition was present on the right side of the face and head. The left side was strong and normally sensitive. The left side of the head was painful to percussion. A peculiar combination of erythropsia in the left eye was present, not only for colours, but also white and black. This had existed since the date of the shock, two and a-half years ago. The acuity of vision in this eye was reduced to 6/13. Another peculiarity of this eye was its binocular or double vision, which is rather paradoxical that a double vision could be produced by the simple rolling outwards of the eyeball. It must be noticed also that there was slight insufficiency of the lips on the right side, while the tongue was inclined to the right. In the right eye there was slight ptosis, with insufficiency of the left abducens, which was all that remained of a reputed squint.

The patient had now been three times hypnotised within the present month, the last twice with a metallic magnet under the head. Immediately before the third experiment, he had the patient examined by an oculist, who found all the above phenomena present. The third experiment was then undertaken, with a remarkable transformation. Instead of all being red, he now saw green and red, later yellow, and then blue, and within 27 hours of the experiment no pathological condition of colour was present; within 48 hours no instability or inclination to the right could be observed. A day later the patient seemed as well as ever he had

been before the shock, and expressed himself gratefully for his speedy recovery.
Volumetrical Changes in the Heart.

Heitler finds, by experiments in the laboratory on animals, that when the pressure is equable the volume of the heart increases if the pulse frequency is reduced, but, on the other hand, if the pulse be increased the volume of the heart is reduced. If the

frequency of pulsation be maintained at a constant rate, and the pressure increased, the volume of the heart is augmented, but if the pressure be reduced the converse is the rule. Hence frequency and pressure are interdependent factors in the morbid changes of the heart.

When both frequency and pressure are changed, the when both frequency and pressure are changed, the volume of the heart varies; as by high pressure and reduced frequency, or by reduced pressure and increased frequency, the heart is decidedly increased, so is the cardiac volume increased by increased pressure and reduced frequency, more than if the increased pressure or the reduced frequency existed alone. The same may be said of increased frequency and reduced same may be said of increased frequency and reduced pressure combined, which increases the volume of the heart more than if one of these factors existed. By modifying these combinations, the intensity of results can be neutralised or altered according to the will of the operator.

There are other conditions which also change the volume of the heart, such as compression of the aorta, which slightly increases it, or compression of the vena

Again, infusions of salt injected into the vena jugularis rapidly increase the size of the heart, while irritating the ischiatic nerve has both properties of increasing and reducing the volume of the heart; but irritating the vagus increases its volume, and dividing both of the vagi has the effect of speedily reducing the size of the heart. Injections of strychnia increase the volume, but they have also the property of reducing it. Injections of digitalis increase the size of the heart at first, but subsequently diminish it. Atropin greatly reduces the size, while nicotine increases the size of the heart for a short time, then rapidly reduces it.

SUPRA-RENAL EXTERPATION.

Porges gave an exhaustive account of his experiments on dogs in determining the amount of sugar in the blood. He finds the normal amount of sugar in the blood does not vary with the amount taken into the alimentary canal, nor with bodily labour, but is regulated by a mechanism in the various organs that keeps the saccharine standard of the blood constant. It is only diabetes mellitus, or extirpation of the pancreas, that permanently increases the amount of sugar in the blood. Hitherto we have no morbid condition pointed out that is the antithesis of this saccharæmia, but Porges tells us he has accomplished this in the laboratory with dogs by extirpating the supra-renal bodies. If this hypoglycæmia can be accomplished, as he affirms, we have now reached a permanent cure for diabetes. This removal of the supra-renal bodies and the deprivation of sugar in the blood has caused Porges to closely examine the blood of patients suffering from Addison's disease, which actually confirms his new-born observation in the laboratory. He is now inclined to believe the adynamia of Addison's disease is due to a sort of aglycæmia or paralysis in the hæmopoietic system. This is an important functional change, as the sugar from the blood plays an active part in muscular contraction. The logic of the experi-ment is: We can cure Addison's disease by extirpating the pancreas, and diabetes by extirpating the supra-renal bodies!

# FROM OUR SPECIAL CORRESPONDENTS AT HOME.

#### SCOTLAND.

EDINBURGH UNIVERSITY LECTURES ON THE HISTORY OF MEDICINE.—Mr. John D. Comrie, M.B., delivered the introductory lecture to the first course on the History of Medicine on January 13th. In this preliminary course he intended to treat of the foundations of Western medicine from the earliest times up to the

declining days of the Roman Empire. Beginning with Assyrian medicine, the doctor is mentioned as early as 2700 B.C., and, of the Code of Hammurabi, nine laws relate to the practice of medicine. From incidental references in these, we learn that the operation for cataract was frequently performed, that unqualified persons attempting surgical operations unsuccessfully had their hands struck off; the highest fee allowed was acqual to are of our money, and was not prid if was equal to 25s. of our money, and was not paid if the patient did not recover. Nearly 1,000 of the 20,000 books in the cuneiform library at Nineveh were medical. Letters from consultants to one another were brown and from these was learn that quarrals were not known, and from these we learn that quarrels were not absent among Assyrian doctors. From the Ebers' Papyrus we know that the doctors in Egypt early attained a position of dignity and usefulness. The antiseptic treatment of wounds was carried out by means of a plaster of crocus and essential oils, and poultices, inhalations, and massage were in common use. Tumours were excised by bronze knives; bleeding was checked by the cautery. The sacredness of the human body debarred amputation except of hopelessly shattered limbs, but fractures were set by splints held in place by linen bands. The shapeliness of broken limbs after treatment by Egyptian doctors was moderately good, but did not reach the success of the Greeks in Plato's time, who seem to have anticipated almost

every device known to this branch of modern surgery.

The LATE DR. DEWAR, PORTREE.—Dr. Dewar,
Medical Officer for Portree, and Medical Officer of
Health for the Skye district of Inverness-shire, died at
Portree on Language with officer of the state of Portree on January 12th, after a short illness. He was a native of Easdale, and graduated at Glasgow in 1887; he came to Portree in 1890. During his practice there he had to cope with several serious outbreaks of typhus fever, and his services on these occasions were specially recognised by Lord Balfour of Burleigh, then Secretary for Scotland, and the Local Government Board. Dr. Dewar enjoyed the confidence and esteem of all classes; he was for 15 years a member of the School Board; was a J.P. for the county, and last year was appointed an Honorary Sheriff substi-

tute for Inverness-shire.

THE LATE DR. LORRAINE, HAWICK.—The death is announced of Dr. Lorraine, who for nearly 20 years has practised in the town of Hawick. He spent several years in Colorado and Texas after qualifying, and he recently went out to the Gold Coast to hold a Government appointment for a year. He was Medical Officer to Stobs Camp and the Hawick Post Office. He was a Unionist in politics, and interested in educational and Church affairs. He is survived by a widow and family.

#### BELFAST

MEDICAL MAN FINED FOR CONTEMPT OF COURT .-An interesting incident occurred at Quarter Sessions at Clones, Co. Tyrone, last week, during the hearing of an assault case before Judge Craig. It was stated that the plaintiff had been attended by Dr. Edward Tierney, J.P., of Clones, and his Honour said that he saw Dr. Tierney in court, and suggested that he should be called. The solicitor for the plaintiff said should be called. that his client was a poor man, and could not afford the doctor's fee in the case. His Honour said that if the doctor had been summoned he would have been allowed his fee, but when a medical man was in court he had no privilege more than any other man. Dr. Tierney refused to be sworn, and after persisting in his refusal, in spite of being told by the Judge that it was his duty to give evidence, he was fined £2 for contempt of Court. Dr. Tierney tried to address the Court, but his Honour refused to hear him. He was understood to say that it was not for the sake of his fee he objected, but for the sake of the medical profession. His protest may have been well meant, but seems to have been rather ill-judged and not calculated to raise the dignity of the profession.

DR. TORRENS'S SUPERANNUATION.—At the last meeting of the Belfast Board of Guardians, the question of a superannuation grant to Dr. Torrens, who re-

signed last month, came up for settlement. Dr. Torrens had discharged his duties to the satisfaction of the Guardians for thirty-three years, and it was agreed to grant him an allowance of £185 9s. 1d., being two-thirds of his salary and emoluments.

COLERAINE COTTAGE HOSPITAL AND FREE BEDS.—At the annual meeting of the Coleraine Cottage Hospital, held last week, the question of curtailing the number of free beds in the hospital was discussed. It appears that by the rules any subscriber of £5 to the funds may recommend a patient for eight weeks' free treatment, and this arrangement has resulted in a considerable annual loss. After a lengthy discussion it was agreed, on the motion of Mr. Barrie, M.P., to reduce the period for free treatment to six weeks.

Anti-Tuberculosis Activity.—The vigour with which the crusade against tuberculosis is being carried on in Belfast was indicated by some remarks at the Public Health Committee of the Corporation last week. The Medical Officer of Health said that he thought the visitation of patients after they left the Forster Green Hospital for Consumption was being rather overdone, as at present they were being visited by a representative from the hospital, by a second from the Public Health Department, and by a third from the Women's Health Association! Surely even Lady Aberdeen should be satisfied with this

activity?

QUEEN'S UNIVERSITY OFFICERS' TRAINING CORPS.-A most successful meeting to inaugurate the new movement in the Queen's University of Belfast was held on Thursday evening, January 14th, when Lord Lucas, Parliamentary Under-Secretary for War, attended and addressed the students. The chair was occupied by the Chancellor of the University (the Earl of Shaftesbury), and among the other speakers were the Commander-in-Chief of the Forces in Ireland (General Sir Neville Lyttleton), and Brigadier-General Wilson. The members of the Corps, who now number well over the hundred, looked very smart in their new khaki uniforms, and they and the other students listened with deep attention to Lord Lucas's explanation of the origin and rapid spread of this movement in the various Universities.

#### LETTERS TO THE EDITOR.

OPHTHALMIA NEONATORUM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,-I have read with considerable interest Mr. Stephen Mayou's lecture on ophthalmia neonatorum, published in The Medical Press and Circular of December 16th last. With most of his remarks I am in cordial agreement, but a few I find myself unable to subscribe.

It is true that during the last few decades there has been a marked decrease in the morbidity of the disease, but, in my opinion, it is going too far to ascribe this, as Mr. Mayou does, exclusively to the introduction of the Credé method of prophylaxis. Other factors have been at work, the most important of which has been the extension of the antiseptic system to lying-in women and their offspring. Over and over again it has been shown that the mere observance of cleanliness in regard to the baby's eyes, as by wiping them free from discharges as soon as possible after the head is born, is capable of reducing the incidence of ophthalmia to a very low point. Mr. Mayou appears to me to make a mistake not altogether uncommon among ophthalmic surgeons when they set out to dis-cuss the prevention of ophthalmia neonatorum— namely, to view prophylaxis from too exclusive a standpoint, and to pin their faith to Credé's method, somewhat to the neglect of other and equally rational means. On other grounds it becomes difficult to account for Mr. Mayou's omission of any mention of the baby's first bath as a potent means of inoculating the eyes with gonorrhoeal or other germs, and of the precautions that should be adopted to prevent that taking place. His neglect, too, of any mention of the necessity of a separate cot for the infant points in the same direction.

Mr. Mayou claims that "Gibson, of Manchester, was Mr. Mayou claims that "Gloson, of Manchester, was the first to demonstrate that by inoculating pus from a gonorrhoeal ophthalmia into the urethra, a typical gonorrhoea was thereby produced." This is news indeed to me. Benjamin Gibson's famous communication, published in the Edinburgh Medical and Surgical Journal of 1807, dealt mainly with the connection between ophthalmia in the baby and fluor albus in the mother, and with prevention of the disease. It did not describe any such piece of experimental evidence as Mr. Mayou hints at. On the contrary, it was Vetch, who wrote in 1820, who furnished the experimental proof of Gibson's deduction by inoculating the urethra with ophthalmic pus, and thereby inducing gonorrhæa

within 36 hours.

Mr. Mayou rightly points out that ophthalmia neonatorum may be confused with a common condition known as "dacryocystitis neonatorum," due essentially to a congenital imperfection of the naso-lachrymal passages, with subsequent infection. This he speaks of as "really a complication of the disease"—i.e., ophthalmia meonatorum—thereby voicing the view of some of the older writers on the subject. Speaking for myself, I am on record in your columns (THE MEDICAL PRESS AND CIRCULAR, 1899), and elsewhere ("Ophthalmia Neonatorum," London, 1907), as believing that the two affections, ophthalmia neonatorum and dacryocystitis neonatorum, have nothing whatever to do with one another. Although I have examined the secrtion from the affected lachrymal passages in many instances, I have never yet succeeded in finding the gonococcus, as Mr. Mayou claims to have done in an unspecified number of cases (Royal London Ophthalmic Hospital Reports, 1908, January, p. 252). The pneumococcus, on the contrary, is, in my experience, extremely common, and so is the staphylococcus pyogenes albus.

I am, Sir, yours truly, SYDNEY STEPHENSON,

Chairman of the British Medical Association Committee on Ophthalmia Neonatorum

33, Welbeck Street, London, W.

MIND AND BODY.—THE INCURABLES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—Those cases which in ordinary practice are beyond hope of recovery, and where treatment is chiefly concerned in relief of pain and the careful prolonging of life, are as a class rather trying to those who have to treat them. It is natural that the sufferers should turn to others who can offer them any hope, and thus Faith-healing and such other modes of treatment as the honest and qualified practitioner must regard with well-merited contempt, may find some support when imagination may be influenced or ignorance imposed upon. It is strange that we should see, in spite of the great improvements in education, that what Sir Dyce Duckworth says in his letter in the Daily Telegraph (Thursday, January 14th) is possible: "I meet occasionally with astounding credulity in bishops and clergy, in peers, judges, and lawyers, to say nothing of the female sex," is an experience that many of us would confirm. The question of interest is, How has this grown up, and what is the real cause of it? It looks as if there are certain forces that are acting in a deleterious manner on the mental conditions of all classes in this country; and as we generally find that it is from disturbance of bodily health, resulting from unhealthy occupations, improper training of the young, and hereditary ills that these mental defects arise, it would be well that the medical profession should use its influence in protecting the feeble public from the delusions into which it may be led, and to which Mr. Henry Sewill has been so often directing attention in his able letters in The MEDICAL PRESS AND CIRCULAR.

I am. Sir, yours truly, M.D., F.R.C.P.LOND.

January 15th, 1909.

THE APPENDIX: ITS USE, ABUSE, AND ITS CLAIMS FOR PROTECTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,-The letter of Mr. Rose, the distinguished Emeritus Professor of Surgery at King's College, which you publish this week, is extremely interesting. If the appendix, as we are told, may be looked upon as acting at the junction of the large and small intestine as a special lubricator for the prevention of constipation, "the most usual cause of appendicitis," how can it be good surgery to treat the organ by "establishing an opening through the abdominal wall," and so allowing permanent escape of its lubricating secretions? No one cuts down upon the appendix unless he has made himself as certain as possible that pathological changes calling for its removal exist. If the appendix on exposure should be found healthy it would be left intact; if diseased it would be removed. Where are the records of cases which support the statement that it is good surgery to leave a patient with a fistulous opening through the belly rather than remove the cause of disease. The suggestion that the appendix performs any function of vital importance is not supported by evidence—at least I have not seen any record of cases in which any disability had been set up by its removal. The suggestion that the appendix should be detached and turned adrift to wander in the peritoneal cavity can surely have originated only in the mind of the editor of a lay paper anxious to manufacture startling head-lines. With regard to great newspapers that publish sensational reports, and introduce without warrant the names of distinguished surgeons, all that can be done is for the outraged men to compel the editors to publish their disclaimers of being parties to the transaction. You, Sir, have abundantly shown—this week again in a most suggestive editorial note that we must free our minds from cant in regarding that great institution the British Press. We must recognise that newspaper managers are business men who, before all things, seek to make money, and that in matters medical they do this first, by giving place, and often their endorsement, to the statements of any quack prepared to pay for the advertisement; and, secondly, by publishing grotesque travesties of science, sensational stories to tickle the ears of the groundlings, and draw pence from the pockets of the ignorant populace.

I am, Sir, yours truly, M.B., M.S.

London, Jan. 15th, 1909.

#### EXPERIMENTS ON PATIENTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your correspondent, George W. F. Robbins, rather reminds one of a legal report which appeared in one of the dailies where the presiding Judge remarked to a counsel engaged in the case, "Mr. So-andso, I do not think you are quite so innocent as you appear to be." However this might be, it seems fairly certain that the statement, "no experiments on patients" would to most minds convey the inference that the hospital adopting such an expression (no other hospital doing likewise) intended to claim on behalf of the public an exemption from "experiments" more or less common to other hospitals. At any rate, to take an analogous case, let us suppose some common boarding-house were to announce on a circular, "No thieves here," I apprehend most of the public would take it that there was less likelihood of their being robbed there than at boarding-houses in general. With regard to Mr. Robbins's advice that other hospitals should follow suit, it is clear if all did the same, that no individual hospital would then gain any special advantage on the one hand, whilst assuming all the hospitals adopted the method, it is possible the announcement would sow broadcast suspicions (much after the fashion of creating false notions in the infantile mind), and which might conceivably turn out to be a greater loss than gain. As Mr. Robbins publicly advises other hospitals to tack on "No ex-

periments on patients," may I take the liberty of suggesting to him the advisability of ripping it off, taking the suggestion for what it is worth?

I am, Sir, yours truly, CLEMENT H. SERS.

Brighton, January 16th, 1909.

RHEUMATOID ARTHRITIS AND ENGLISH HOTELS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,-Whilst agreeing in the main with Dr. Murrell on this subject, permit me to say that I think his adverse comments on English hotels, in comparison with those on the Continent, unnecessarily sweeping. In his letter in your last issue he says:—"The great objection to our English health resorts is the expense necessarily incurred at anything like a decent or socalled first-class hotel. At many of these they refuse during the season to quote inclusive terms even for a prolonged stay, and 25s. a day is the average charge for room and board, even when that room is at the top of the house and of the size of a fairly capacious wardrobe." I have a pretty extensive knowledge of hotels both in this country and abroad, and if he will pardon my saying it, I have never yet come across an establishment at any of our health resorts, where such exorbitant terms were demanded. I know Bath, Buxton, Cheltenham, Matlock Bath, Brighton, Torquay, and Hastings well, and have staved within the last five or six years at the largest and what are considered the best hotels of nearly all these places. the Royal Hotel, Matlock Bath, which is much frequented by the profession and by patients because of its splendid system of baths, I was asked but 15s. per diem by the week for an excellent bedroom, full board and attendance. At the Grand Hotel, Brighton, I paid but 18s. in the height of the season, and at the Queen's Hotel, Hastings, a little less for the same accommodation. Of Harrogate I cannot speak from personal experience; but I need not enlarge on the subject except to say that I fear we are too prone to send our patients abroad, when in many cases they would do better at our health resorts at home.

I am, Sir, yours truly,

M.R.C.P.LOND.

January 18th.

#### OBITUARY.

#### DR. B. S. BOOTH.

THE oldest member of the medical profession in Newry has just passed away in the person of Dr. Biabazon S. Booth, at the advanced age of 79 years. Early in life he adopted the medical profession, and in 1858 he went to India, and was shortly afterwards appointed House Surgeon and Secretary to the native Hospital at Calcutta. This appointment he held for six years, when he became Civil Surgeon at Tirhoot. On his return to Ireland in July, 1874, he was elected Medical Officer of the Newry General Hospital, and that position he held until March, 1894, when he resigned owing to failing health. On the occasion of his retirement he was made the recipient of an address and presentation from the people of Newry for the care and attention he had always shown the patients at the hospital.

#### DR. J. D. CRONIN, M.B.

WE regret to record the death of Dr. J. D. Cronin, of 75 Lower Mount Street, Dublin, at the advanced age of 87. The deceased was formerly a Fleet Surgeon in the Royal Navy, and retired from active service some years ago. He had received the Medal for the Bellin Commission. for the Baltic Campaign, 1854-5.

MEASLES is raging at Bromyard, Herefordshire, and all the Council schools have been closed. Nearly 200 cases have been reported.

## Summary of Recent Medical Literature, English and Foreign.

: pecially compiled for THE MEDICAL PRESS AND CIRCULAR.

A Digest of 265 Cases of Malignant Disease of the Uterus, treated in the New Hospital for Women.—
Louisa E. Anderson and Kate Platt (Journ. Obst. and Gyn., Vol. XIV., No. 6). During thirteen years, 265 cases were treated. Of these there were 217 cases in which the disease affected the cervix, and 48 cases in which it effected the funder. The records of the which ite disease anected the cervit, and 40 cases in which it affected the fundus. The records of the cases of malignant disease of the cervix in which hysterectomy was done show that in seven years, 1895-1901, the abdominal route was employed in 2, and the vaginal in 25 cases; whereas in the following six years, 1902-1907, 58 abdominal and only 2 vaginal hysterectomies were performed for the same conditions. At first the abdominal operation differed little from that done for fibroids. At the present time the method consists of the removal of the uterus and appendages, the broad ligaments and the upper part of the vagina, the uterine arteries being divided well outside the line of the ureters. If the condition of the patient permits, a systematic search for and removal of lymphatic glands is carried out. The incision in the vaginal roof is left open, and a gauze drain passed through to drain the large cellular space, which is opened during the operation. This method of draining has been modified in some of the recent cases, and the vagina only drained, but the results have not been favourable; there has been more tendency to cystitis, and in some cases blood clot has collected and cellulitis resulted. After vaginal hysterectomy patients used commonly to die from local recurrence in the vaginal vault. Out of the 29 cases in which vaginal hysterectomy was done for cancer of the cervix, the disease recurred in 12 cases in the vaginal scar within a few weeks from the time of operation. After a complete abdominal panhysterectomy, metastasis is most likely to affect the iliac glands. Hence the importance of their removal at the time of operation, if possible, and even in those cases in which it seems as if satisfactory removal has been accomplished, the patient may develop symptoms of internal recurrence a year or two later. Of the 29 patients upon whom vaginal hysterectomy was performed for cancer of the cervix, one is alive and well seven years after the operation; two remained well for two years, and in 12 the disease recurred very soon after the operation; the other cases have been lost sight of. The after-results of 58 abdominal hysterectomies for cervical cancer, though not good, are much better than the vaginal operation. Twentyare much better than the vaginal operation. Twenty-six cases are alive and well between 1½ and 4 years after operation, 11 cases had recurrence within a year, 6 cases recurred in from 1 to 3½ years; 15 cases cannot be traced. The after-results of fundal cancer are much more satisfactory. Nine cases were operated on per vaginam, and 30 by the abdomen; of these, 26 have remained well for from 2 to 7 years; 7 developed recurrence in from 1 to 5 years; 3 patients died, and 7 cannot be traced. A large number of the cases of fundal cancer—17 out of 27—were associated cases of fundal cancer-17 out of 37-were associated with fibroids, while in cases of cancer of the cervix this association was relatively rare, only occurring in 4 cases out of 216. The large proportion of cases of cancer of the endometrium which were accompanied by fibroids in the uterine wall suggest that it is necessary to regard all 6 beside with a case. sary to regard all fibroids with suspicion and to advise their close supervision and their removal as soon as they cause symptoms. By far the greater number of specimens of carcinoma of the cervix are of the squamous-celled variety. The authors say:—"It is surprising in how many cases careful search is rewarded by the finding of one or more well-defined whorls, and on more than one occasion this has determined the inclusion among the epitheliomata of a tumour which might otherwise have been described as columnar carcinoma. The tumours of the fundus columnar carcinoma.

consist entirely of adeno-carcinomata, of which all varieties are present. The authors point out that the vast proportion of women with cancer of the cervix are over 30, and have had children, while the majority of those with cancer of the fundus are over 50, and have not had children, but there are exceptions to both rules.

Physiological Anæsthesia During Labour.—Dr. R. E McKerron (Journ. Obst. and Gyn., Vol. XIV., No. 6) records an interesting case under this heading. He was called to a woman in her fourth confinement. Labour began in the forenoon, at 5 p.m. the os was almost half dilated. At 7 p.m. the membranes were ruptured and the head at once descended and engaged the os. The pains became frequent and strong, and were attended with so great suffering that he decided to give chloroform earlier than usual. However, before the anæsthetic could be begun an unusually strong pain came on; at its height the patient gave a loud scream and at once became unconscious. Her breathing was heavy and almost stertorous; her face somewhat flushed; the eyes fixed in a vacant stare; the pupils dilated, but equal; the conjunctival reflex completely abolished. She was quite insensible to pain, but in all the limbs reflex movements could be elicited. There was no muscular twitching at any time, merely general and complete relaxation. Powerful uterine contractions, accompanied by strong down-bearing efforts, continued to occur every three minutes. The coma remained unaltered, and the conjunctival reflex absent till delivery was completed. Immediately the child was expelled she suddenly woke up, consciousness being regained almost as abruptly as it had been lost. There was no mental confusion, but she remembered nothing, had felt no pain, and was surprised to learn that the child was born. The same writer reports a case of fatal hæmorrhage from the vagina in a newborn child. On the fourth day after birth there was a slight discharge of blood from the vagina. The hæmorrhage continued, but was little more than a stain and did not seriously affect the child. On the eighth day the bleeding increased, and on the following day was comparatively profuse. Cotton wool soaked in adrenalin was passed into the vagina, but did not arrest the bleeding. The next morning the child was blanched and pulseless; several diapers had been soaked with blood from the vagina, while from an insignificant scratch on the lip over a drachm had been lost. The vagina was plugged with cotton wool and the bleeding ceased, but the child died a few hours and never any sign of intestinal hamorrhage. No reliable family history could be obtained, but the mother stated that she suffered from eachymosis on the slightest injury. That fact and the bleeding from the scratch on the lip place the hæmophilic nature of the case beyond doubt.

The Subcutaneous Catgut Suture.—W. E. Fothergill (Journ. Obst. and Gyn., Vol. XIV., No. 6) has, by way of experiment, used the subcutaneous stitch for closing every incision made by him during the past year, with the exception of one or two emergencies. The result is that he has formed a definite conclusion to the effect that this method is a trifle better than any other which he has tried or has seen. He sums up the advantages as follows:—(1) It is rapid as compared with other methods; (2) it leaves a less conspicuous scar; (3) there are no stitches to be removed; (4) if suppuration occurs it is merely superficial and does not affect the deeper portions of the wound. The risk of hernia is

thus diminished; (5) suppuration is less likely to occur in this than in any other form of suture. The source of infection, at the present time, is generally the skin of the patient. In the subcutaneous suture, apart from the incision itself, only two holes are made through the skin. This fifth advantage is the most important and the one on which the writer wishes to base his suggestion that the subcutaneous continuous suture is worthy of extended trial by all abdominal surgeons.

Treatment of Fractures of the Base of the Skull .-Maclaren (Brit. Med. Journ., 26th December, 1908) describes two cases of this injury. The author considers that fracture through the petrous portion of the temporal bone, opening into the external meatus, is most likely to be followed by septic infection of the cranial cavity. He uses dry boric acid to keep the external ear and meatus in an aseptic state. As the powder dissolves in contact with the discharge, it cannot form a retaining plug. The writer recommends trephining in basal fractures. The continual oozing of cerebro-spinal fluid is an important factor in the evolution of septic meningitis; nor does it establish a water way to the interior of the skull, but it produces a sodden state of the tissues very favourable to sepsis. A trephine opening and drainage of the subarachnoid cavity prevents the fluid being under tension, and allows it to escape by an arranged safe route. Tension is equally relieved by as spinal as by a cephalic drain, but in head injuries there is a practical advantage in placing it at the seat of the injury, in that it allows an investigation of the skull and brain at that point which is likely to have suffered from the direct violence. The opening for drainage is large also, and not liable to the blocking which may easily close a small tube as used in lumbar puncture.

Appendicostomy in Diffuse Septic Peritonitis.— Billington (Brit. Med. Journ., 9th January, 1909) points out that in his experience, and in that of many others, it is often impossible to introduce into the circulation the large quantities of fluid recorded by Murphy, of Chicago, in cases of diffuse septic peritonitis, where it is important to prevent peristalsis by withholding all fluid and food by the mouth. In such cases, the writer has utilised the appendix for the purpose of introducing fluid into the large bowel with marked success. For instance, in peritonitis following the perforation of a gastric ulcer, an incision is first made over the lesion, which is treated and drained through the wound. Then, instead of making a suprapulic puncture to allow of the introduction of a rubber tube into Douglas's pouch, the abdominal cavity is again opened by a small vertical incision over the lower part of the right rectus. The appendix is pulled out, the distal portion cut off, and the stump fixed to the upper angle of the wound. A small rubber catheter is passed into of the wound. A small rubber catheter is passed into the cacum, the other end projecting through the dressings, when they are put on. A large rubber drainage tube is passed to the bottom of Douglas's pouch through the lower part of the wound. In bed, the patient is placed in Fowler's position, the catheter being connected to a tank containing warm salt solu-tion, and which stands on a table at the bedside, and not more than three inches above the plane of If the peritonitis is due to disease of the appendix, the part nearest to the cacum is often comparatively healthy, and if not a small portion of the carcal wall nearest the surface is sutured to the skin. Not more than one pint per hour is admitted into the bowel to avoid distension. When absorption ceases, as much fluid is evacuated from the rectum as is introduced into the cæcum, and the supply is then cut off. The catheter is not left in longer than forty-eight The mucous membrane of the stump of the appendix is then removed, and the opening closed by uniting the sero-muscular coats. Finally, any adhesions between the skin and the stump are gently broken down, and the latter allowed to tetract. The advantages of this procedure are: The quantity of fluid admitted can be regulated exectly, and the whole large intestine takes part in its absorption. The patient suffers practically no discomfort. Stimulants and nutrients can be rapidly administered.

#### REVIEWS OF BOOKS.

DISEASES OF THE HEART. (a) This is the most recently translated volume in 'Nothnagel's Practice." Of text-books on diseases of the heart there are many which are excellent and sufficient. Unfortunately, some of the best are by foreign authors, and as many medical men are unable to read any language but their own it becomes necessary to have these works translated. In the original it has been recognised by specialists as an authoritative treatise on its subject. Prof. von Jürgensen writes on cardiac insufficiency, endocarditis, and valvular disease; while Prof. Krehl treats of diseases of the myocardium and nervous affections of the heart. The section on diseases of the pericardium has been entrusted to Prof. von Schrötter. These three names are a sufficient guarantee as to the excellence of the monographs comprising this volume. Turn where we will, we find the same painstaking care in statements of facts and theories in evidence.

As regards the work of translation, this has been carefully carried out by the American translator. We have taken the trouble to compare at random one or two passages with the original, and find that the translation is accurate, and represents in a wonder-fully pleasing manner the sense of the writers. Few alterations or additions have been attempted. the most part these consist in adapting the medicinal nomenclature to the United States Pharmacopæia. A few matters of interest, published since the original work was issued, have been added in brackets. These include important American and English contribu-tions to the subject. As a work of reference on diseases of the heart, we feel certain that this volume will take its place alongside the other excellent English treatises on the subject. It presents all that is best in German teaching, and knowing as we do the thoroughness with which the original writers are in the habit of carrying out their investigations, we have no hesitation in claiming for this translation a hearty welcome by specialists in this country. This, the latest volume in the English edition of "Nothnagel's Practice," is a noteworthy addition to a most excellent series, which is certain to make its influence felt upon English teaching and practice.

THE RECTUM: ITS DISEASES AND DEFECTS. (b)
This very fine volume is the lineal successor of a former and smaller work published by Sir Charles Ball in 1887 on "The Rectum and Anus, their Diseases and Treatment." The latter work is now out of date and has been withdrawn from circulation. The present volume is an entirely new book on the same subject, but upon different lines. It is founded mainly on the Lane Lectures on Diseases of the Rectum which were delivered by the author at San Francisco in 1902, and on the Erasmus Wilson Lectures on Adenoma and Adeno-carcinoma of the Rectum, delivered at the Royal College of Surgeons in London in 1903. The result is a concise work which, while it deals most fully with the modern aspects of its subject, does not digress into historical matters which, though interesting, are unessential.

The book begins with a well-written chapter on rectal anatomy, in the course of which the author acknowledges the work which has been done in the Dublin School of Anatomy in recent years in regard to the lower bowel. The chapter is illustrated by some very beautiful original drawings made from frozen sections and dissections. Then follow three

<sup>(</sup>a) "Diseases of the Heart." By Prof. Th. v. Jürgensen, of Tübingen: Prof. L. v. Schrötter, of Vienna; and Prof. L. Krebl, of Greifswald. Edited with additions by Geo. Dock, M.D., Professor of Medicine and Clinical Medicine, University of Michigan. Authorised

cine and Clinical Medicine, University of Michigan. Authorised translation from the German, under the editorial supervision of Alfred Stengel, M.D., Professor of Clinical Medicine in the University of Pennsylvania. Philadelphia: W. B. Saunders Company. (b) "The Rectura, its Diseases and Dovelopmental Pefects." By Sir Charles B. Ball, M.Ch., F.R.C.S.L., Hon, F.R.C.S.Log., Regius Professor of Surgery in the University of Dublin; Surgeon to Sir Patrick Dun's Hospital; Hon. Surgeon to the King. London: Henry Frowde, Hodder and Stoughton. Pp. xiv and 328, with five plates and 181 illustrations in the text. 1998.

chapters on developmental defects, many interesting specimens of which are shown in the illustrations. An interesting but, perhaps, rather short chapter on rectal diagnosis follows. We note that the author is sceptical as to the value of the rectoscope and the colonoscope for the diagnosis and treatment of highlying disease of the rectum.

The chapter on infective diseases is longer. In addition to the more ordinary forms of infective disease, gonorrhœa, diphtheria, tuberculosis, syphilis, and actinomycosis of the rectum are discussed. Fig. 59 has been accidentally reversed. There is a fine microphotograph of spirochate pallida, obtained from an anal condyloma. The next six chapters are devoted to ulceration, fistula, stricture, fissure, and prolapse. We look with interest for the author's opinions on the radical treatment of rectal prolapse. We note that he considers that the modern improved methods of operation give such good results that all patients, save decrepit old people, should be advised to submit to operation. Van Buren's lineal cauterisation is sometimes of use. Narrowing of the anus by circular cau-terisation, or by plastic operations is an unscientific and unsatisfactory way, as is Thiersch's operation. "It cannot, of course, be claimed that any surgical procedure can completely restore the relaxed muscles and ligaments of the pelvic outlet; recent methods, however, show that, as in nephropexy and hysteropexy, much may be done by fixation of the rectum or colon, either alone or in conjunction with myorraphy (? myorrhaphy) of the levator ani, and narrowing of the lumen of the rectal ampulla by rectoplicature."

The next three chapters deal with piles, and are, as one would expect, excellent. The pictures, also, are very good, Plate IV. being especially fine. The next four chapters deal with benign and malignant tumours and their treatment, The various operations per-formed for rectal cancer are described fully and well illustrated.

The remaining chapters of the book deal with colotomy, foreign bodies in the rectum, injuries, neuroses, pruritus ani, and diverticula. In the chapter on pruritus the operation originally described by Sir Charles Ball is detailed and illustrated. It has proved of considerable benefit, not only in the hands of its originator, but in other hands also.

We heartily congratulate Sir Charles Ball both on the originality and merit of his work, and on the beauty of the idlustrations. The book reflects the greatest credit on the Dublin School of Surgery, as well as on its distinguished author.

### MEDICAL NEWS IN BRIEF.

Royal College of Surgeons of England.

At the quarterly meeting of the Council, held on Thursday last, Mr. Henry Morris, President, in the The formula for a new by-law relating to the admittance of women to the examinations for the diplomas of Fellow and Member and of the Licence in Dental Surgery was submitted, and was referred to a committee to take into consideration and report thereon to the next meeting of the Council. A vote of thanks was passed to Mr. E. L. Gruning for his gift of skulls from Cook Islands of pathological as well as of anthropological interest. Mr. Henry T. Butlin, F.R.C.S., was re-elected a member of the Court of Governors of the University of Birmingham. Having passed the required examinations and conformed to the by-laws, Mr. Norman Cecil Rutherford, M.B., B.S., Edinburgh University and London Hospital, was admitted a Fellow of the College. Diplomas of the College Licence in Dental Surgery were granted to the following successful candidates: -Thomas Percy Brown, Birmingham University; Robert Hope, Harvard University and Guy's Hospital Dental School; Joseph Jackson Wardill, Charing Cross and Royal Dental Hospitals; Hugh Parry Williams, Middlesex and National Dental Hospitals; and Augustus Vallack Wallis, Charing Cross and Royal Dental Hospitals. Alleged Abortion at Cardiff.

THE Cardiff Deputy Stipendiary (Mr. E. M. Jones) on January 14th proceeded with the charge against Henrietta Veall (45), of having unlawfully used an instrument on Clara Lamprey on divers dates between July and November, with intent to procure a miscarriage. Mr. Harold Lloyd defended. Mrs. Lamprey, who seemed weak, appeared in court for the first time.

In the course of her evidence, Mrs. Lamprey said that her husband, Adam Lamprey, was a carpenter. She had known defendant for about four or five years, and in July last she met her in Canton and told her she was enciente. Prisoner told her that she would call next morning, and, in fact, did call, and visited her every day for nearly a fortnight. During her operations Mrs. Lamprey said that some days she felt sharp pain. After she ceased to visit she felt very ill, and lost a quantity of blood for about three weeks or a month. Eventually she was compelled to take to her bed, and sent for Dr. Campbell. A monetary arrangement had been arrived at with the prisoner, who told witness that she usually received a guinea. She was paid about 18s. in all.

Cross-examined by Mr. Harold Lloyd: Had you made up your mind to get rid of the child at all costs? -No, I had not thought of it until I had a conversa-tion with her.

Emma Sellers, a widow, referred to a conversation she had with Mrs. Lamprey some six or seven weeks before prisoner was arrested. The prisoner used to call at Mrs. Lamprey's on several days. When prisoner

came witness used to go away and leave her. Amelia Phillips, a servant girl. also gave evidence to the effect that she had seen prisoner calling at the house.

Dr. Hy. Campbell said that he was first called to visit Mrs. Lamprey on November 1st. He examined her and found her in a high state of fever. He afterwards made an examination in consequence of what she told him, and took for granted that there had been a miscarriage through abortion. He questioned her on that, gave her medicine, and treated her. On November 11th he was of opinion that she was dangerously ill, and not likely to recover, and her depositions were

taken, and an operation was performed on the 14th.

The prisoner was committed for trial at the next Assizes.

Mussels and Typhoid-Atherton Medical Officer's Report.

An outbreak of typhoid, which lately assumed serious proportions, has occurred at Atherton, and in a report which Dr. Marsh, the Medical Officer for the district has submitted to the District Council on the matter he says:—"In 13 cases we found that the sufferers had partaken of mussels. The time or period of the year, I take it, is no excuse for a typhoid epidemic, though there is no doubt that the disease occurs more frequently in the autumn, and, in all probability, the cause of this is the abundance of flies which are in evidence at that time. In the present year, for instance, the number of flies at or about the end of September amounted to a perfect plague. In the light of present knowledge with respect to the danger of eating mussels, etc., it seems advisable that greater powers should be given to the county and local authorities to deal with any such food that is found to carry any disease, or as likely to cause disease. It seems hard that persons should contract typhoid from eating shell-fish, etc., which come from a river or bed known to be affected by sewage, and yet even the county authorities have not control over that river should it happen to be tidal. I am informed that in almost all cases the patients who had partaken of mussels suffered from the disease in a very severe form, and of these patients there have been four deaths, or rather more than 26 per cent. of the cases attacked."

The Peculiar People.

BEFORE Mr. Justice Grantham, at the Central Criminal Court on January 12th, George Hornsnell, a labourer, and his wife, Eliza Hornsnell, of Plaistow, members of the Peculiar People, were

put upon their trial charged with the manslaughter of their daughter Phyllis, aged 4 years, by wilfully neg-lecting to call in medical aid in time of illness.

Mr. Symons, counsel for the prosecution, said the sect did not believe in medical aid in case of illness, but rather in the efficacy of prayer. The child Phyllis was one of eleven children, and on November 29th she was seized with measles, followed by pneumonia, from which she eventually died. It was admitted that, with the exception of calling in a doctor, the parents did everything they could for the child. When the pneumonia set in on December 5th, according to the usual practice of the sect an elder was called in, and the child was prayed over and anointed. A week later the parents invoked the further assistance of the elders, and a special prayer was offered up in their church. On Decmber 17th, however, the child died.

Martha Worm Wild, the wife of an elder, spoke as to the child's illness, and to calling in her husband to pray over and anoint the child.

The Judge: Could you not have prayed over her?-

I did, and God heard my prayer.

The Judge: But the child died. Why did you not call in a doctor?-We act upon the words of St.

James.

The Judge: Our Saviour did not tell you not to call in a doctor, and you appear to place more reliance on the words of an Apostle than upon the words of our Saviour.—Witness replied that she had not read in the Scriptures that Christ told them to call in a doctor.

The Judge: Christ said, "They that are whole need not a physician," which seems to infer that those who

are not whole do.

Dr. Kennedy expressed the opinion that the child's life with medical aid would certainly have been pro-

The jury found both prisoners guilty.

The Judge sentenced each prisoner to three months' hard labour.

#### Hospital Tragedy.

AT Chelsea Mr. C. L. Drew conducted an inquiry regarding the death of Charles Stephen Welch, a patient at Brompton Hospital for Consumption, who threw himself out of a window with fatal results.

Annie Maria Bayes, a sister at the hospital, said that Welch was a very nervous patient. As he said he wished to go home, witness told the porter to be on the alert to prevent him from leaving. Afterwards he became more rational. There were no bars to the windows in the wards, which were always kept open for the sake of the open-air treatment of patients.

William Thomas Beasley, porter at the hospital, stated that on Saturday morning, about 9 o'clock, he was put outside Welch's ward because the man was supposed to be out of his mind. Witness was told to prevent him from leaving the ward, a window in which was open. Suddenly the sister called to witness, and he saw Welch trying to get out of bed. Witness advised him to lie down, and covered him up. Suddenly he bounded out of bed and sprang on to the window-sill, but witness managed to catch him by his shirt and one of his wrists. The sleeve of his shirt, however, tore right off, and he fell into the yard 40 ft. below. Witness believed the man was insane.

The Coroner: Can you say why an insane man was

allowed in a ward with an open window?--I cannot. Dr. McNalty, Resident Medical Officer, said that when he saw Welch he did not think that there was

anything mentally wrong.

The jury returned a verdict of death from misadventure, stating that the deceased man jumped from a window not knowing what he was about.

### Society for Relief of Widows and Orphans of Medical

AT the Quarterly Court of the Directors of this Society, held on Wednesday last, Dr. Blandford, President, in the chair, the deaths of three members were reported, among them being that of Sir Henry Pitman, a Vice-President of the Society. A vote of condolence

to Lady Pitman was passed from the Chair. Three new members were elected. A sum of £528 had been distributed among the annuitants of the charity as a Christmas present, each widow receiving Lio, each orphan £3, and each orphan on the Copeland Fund 65. Since the last Court one of the annuitants of the Charity had died, her husband had paid in subscriptions £33 12s., and died in 1855, since that date his widow received from the Society in grants the sum of £3,300, a striking instance of the advantages of joining the Society. The sum of £1,242 10s. was voted for the half-yearly grants to the widows and orphans at present on the books of the Society.

Relief is only granted to the widows and orphans of deceased members, and during the past three months five letters had been received from widows of medical men, left penniless, asking for relief, but this had to be refused as their husbands had not been

members of the Society.

Membership is open to any registered practitioner, who at the time of his election is residing within a 20-mile radius of Charing Cross. Full particulars and application forms for membership may be obtained from the Secretary, at the offices of the Society. 11 Chandos Street, Cavendish Square, W.

#### Doctor's Death on a Liner.

DR. ALEXANDER HENRY McDougal, the son of a Manchester alderman, and a Medical Officer in the service of the Holt Steamship Company, of Liverpool, was found dead in a berth of the liner Zaanstroom at Hull. He was returning to England from Amsterdam, where he had arrived after a voyage to the West Coast of Africa. He had been ill for some time, and a brother had come to Hull to meet him.

#### Royal Army Medical Corps.

THE following appointments were officially gazetted

on Friday last:

Surgeon-Lieut.-Colonel F. W. Gibbon, from the Tyne Division (Electrical Engineers) Royal Engineers (Volunteers), to be Lieutenant-Colonel, with precedence

(Volunteers), to be Lieutenant-Colonei, with precedence as in the Volunteer Force, April 1st, 1908.

1st London Territorial Division.—Surgeon-Lieut.—Colonel and Honorary Surgeon-Colonel J. Cantlie, M.B., F.R.C.S. (Eng.), from the Honorary Coloneloy of the Eastern Command, Maidstone Companies, and the London District, London Companies Royal Army Medical Corps (Volunteers), is appointed to the Honorary Colonelcy of the division, with precedence as in the Volunteer Force, April 1st, 1908.

#### Conjoint Examinations in Ireland.

THE following candidates have passed the First Professional Examination of the Royal College of Physicians and the Royal College of Surgeons, January, 1909:—M. J. Ahern, A. T. Cannon, T. F. Collins, H. J. Cotter, C. J. Hegarty, C. Hennessy, C. F. D. Kelly, F. Mulcahy, A. Verling.

#### Measles Epidemic in Nottingham.

THERE is an epidemic of measles at Nottingham. Evidences seem rather to point to its further increase. The significant point about the present visitation is that it has spread most during the period at which the children have been absent from school, for it is usually urged that the closing of schools is the most effective method of checking the spread of these infectious diseases.

So far the Nottingham Education authorities have only found it necessary to entirely close one school, but several of the infant departments and classes for younger scholars, in all parts of the city, are temporarily suspended.

THE members of the Blackwater Fever Expedition of the Liverpool School of Tropical Medicine have now returned to England. The expedition consisted of Dr. J. O. Wakelin Barratt and Dr. Warrington Yorke. The expedition left England on August 12th, 1907, and returned on the 5th inst., remaining in Nyasaland for fourteen months.

#### NOTICES TO CORRESPONDENTS. &c.

CORRESPONDENTS requiring a reply in this column are par-ticularly requested to make use of a Distinctive Signature or Instial, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much con-fusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January let and July let respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messra. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messra. Dawson and Sons are our special agents for Canada.

#### ADVERTICEMENTS.

ADVERTICEMENTS.

FOR ONE INSERTION:—Whole Page, 25; Half Page, 23 10s.; Quarter Page, 21 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 Insertions, at 23 10s.; 26 at 23 3s.; 52 insertions at 23, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.:—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

M.R.C.S., L.R.C.P. (Londou).—As such posts can always command a supply of candidates from young qualified men, without payment, it is obvious that the offer of an honorarium is not regarded as a necessary feature in the case.

"XRAYARR."

#### "XRAYSER."

The flexibility and adaptability of our language in meeting the demands of the times, are illustrated again in the suggestion that the man who works with the X-Rays should be called an "Xrayser." The man, too, who practices Mr. Keetley's operation, might be called an "Appendicoster."

SUBBITON FRACTITIONER.—We see no objection to your name being published as Hon. Secretary of the entertainment—especially as there is a joint secretary and the proceeds are for a medical charity. Why not write for an opinion on the point to Dr. Bateman, Medical Defence Union, Trafalgar Square, London, W.C.

ERYTHEMA NODOSUM.

A correspondent has written to ask if erythema nodosum occurs elsewhere than on the legs. In a case recently under his care there were apparently typical swellings over the legs, but he was somewhat doubtful about the diagnosis as there was a similar swelling on one thigh near the groin, and both ears were swollen and one was excertated Erythema nodosum ma- occur on almost any part of the body, as well as on the legs. It is often accompanied by other forms of erythema.

BBDFORD .-- Your communication came to hand as we were "at

B. K. G.—The matter is one of so controversial a nature that we cannot open our columns to its discussion in the form of an anonymous communication. If our correspondent, however, is prepared to append his name to his letter, we will publish it.

### Meetings of the Societies, Tectures, &c.

Wednesday, January 20th.

Rotal Society of Medicine (Section of Anesthetics) (20, Hanover Square, W.).—8.30 p.m.: Special General Meeting: To Consider the Advisability of Legislation to Control the Administration of Anesthetics. The proposed Bill, which is given in full in the British Medical Journal, Dec. 5th. 1996. Supplement p. 302, will be taken as the basis of the Discussion. North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—Clinics: 2.30 p.m.: Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks).

British Balneological and Climatological Society (20, Hanover Square, W.).—5 pm.: Dr. Buckley (Buxton): Intestinal Lavage on the Plombleres System.

ROTAL MICROSCOPICAL SOCIETY (20, Hanover Square, W.).—8 p.m.: Right Hon. Lord Avebury: On Seeds, with Special Reference to British Plants (Presidential Address). Exhibition of Forsminifers dredged from off the Coast of Somaliland.

Therrich (Permatological Section) (20, Hanover Square, W.).—4 p.m.: Annual General Meeting. Clinical Case: Dr. Pernet: A Case of Granuloma Annulare (shown at a previous meeting). (And other Cases not yet notified.)

ROTAL SOCIETY OF MEDICINE (Neurological Section) (20, Hanover Square, W.).—8.30 p.m.: Short Papers: Dr. A. E. Russell and Mr. P. W. G. Sargent: Apoplectiform Cerebral Hemorrhage; Operation: Execuation of Blood; Recovery. Dr. Henry Head: A Case of Fractured Spine illustrating Various Forms of Sensory Loss. Dr. S. A. K. Wilson: A Case of Thrombosis of the Left Posterior Inferior Cerebellar Artery.

#### Appointmenis.

Hospital, Greenwich, has been appointed Secretary of University College Hospital.

M.B.Lond., L.R.C.P.Lond., M.B.C.S., Assistant Medical Inspector of Schools by the Somerset County Council.

County Council.

BIGGS, GEORGE NIXON, M.B., B.S.Durh., Aural Surgeon to the Evelina Hospital for Sick Children.

BROWN, W. BRODIE, M.D., C.M.Aberd., Medical Officer and Public Vaccinator for the Parish of Lumphanan.

CORBETT, WILLIAM EDWARD MANDERSON, L.R.C.P. and Medical Inspector of Schools for Stonehouse by the Devon Education Committee.

FREMANTLE, F. E., M.B.Oxon., D.P.H.Eng., to the Edward Jenner Lectureship on Public Health at St. George's Hospital Medical School.

School.

HOWARD RUSSELL, M.S.Lond., F.R.C.S.Eng., Surgeon to the

HOWARD RUSSELL, M.S.Lond., F.R.C.S.Eng., Surgeon to the Poplar Hospital.

MARNAN, JOHN. M.B., B.Ch., B.A.O.Dub., Medical Officer at the Gloucester County Asylum.

SANDFORD, GEORGE CALROW, M.D., C.M.Edin., Public Vaccinator for Devonport.

TCHATROVSET, BARBARA, M.D.Lond., Assistant School Medical Officer by the London County Council.

#### Vacancies.

Sussex County Hospital, Brighton.—Stephen Ralli Memorial.—
A Pathologist.—Salary, £350 per annum, and half the fees earned in private practice. Applications to the Secretary of the Hospital.
London Fever Hospital, Liverpool Road, N.—Assistant Resident Medical Officer.—Salary, £150 per annum, with residence and board. Applications to the Secretary.
Bristol General Hospital.—Senlor House Surgeon. Salary, £120 per annum, with board, residence, etc. Applications to the Secretary.
Bolton Union.—Resident Assistant Medical Officer.—Salary £170

Bolton Union.—Resident Assistant Medical Officer.—Salary, £170

Bolton Union.—Resident Assistant Medical Officer.—Salary, £170 per annum, with furnished apartments, light, washing, and attendance. Applications to H. I. Cooper, Clerk to the Guardians, 28, Mawdsley Street, Bolton.

Manchester Corporation.—Monsall Fever Hospital.—Senior Assistant Medical Officer. Salary, £200 per annum, with board, lodging, and washing. Applications to the Chairman of the Sanitary Committee, Public Health Office, Town Hall, Manchester.

Surrey County Lunatic Asylum, Brookwood, near Woking.—Second Assistant Medical Officer. Salary, £200 per annum, with board, lodging, and laundry. Applications to the Medical Superintendent of the Surrey County Lunatic Asylum, Brookwood, near Woking.

Epileptic Colony, Langho, near Blackburn.—Medical Superintendent. Salary, £250 per annum with furnished residence, washing, and garden produce, etc. Applications to Henry Woodhouse, Clerk to the Joint Committee, Chorlton Union Offices, All Saints, Manchester.

#### Marriages.

CLOTHIER—Francis.—On Dec. 19th, at St. Andrew's Church, Calcutta, Henry, eldest son of Henry Clothier, M.D.Lond., of Innerwyke Manor, Felpham, to Elsie Francis, daughter of Mrs. Laidlaw, 44, Prince's Gardens, S.W.

MONEY—LEALE.—On Jan. 13th, at St. Sampson's Church, Guernscy, Lleut, Brien Money, R.N., son of the Rev, Granville Money, Rector of Byfiest, to Florence Mary, daughter of Josish Leale, M.R.C.S., of Vale House, Guernscy.

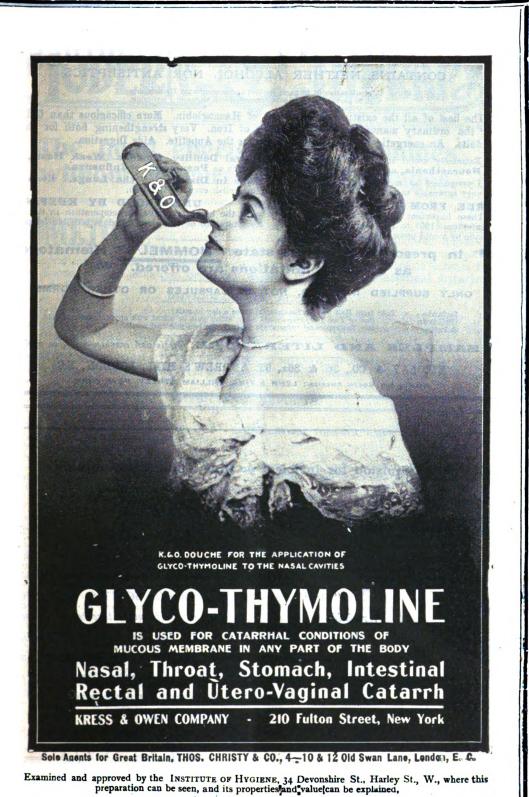

MACANDEW—WIGMORE.—On Jan. 13th, at St. Like's, Chelsea, William D. Macandrew, son of the late W. Macandrew, J.P., of Westwood, Colchester, to Grace Nins Wigmore, youngest daughter of William Wigmore, M.R.C.S., L.R.C.P., of Inverness Terrace, London.

#### Deaths.

COPLAND.—On Jan. 16th, at Sheerness, John Brightman Copland, M.R.C.S., L.R.C.P.Lond., aged 29.

NOBLE.—On Jan. 16th, at 167. Kennington Park Road, London (suddenly), James Black Noble, M.R.C.S., L.R.C.P., aged 50.

SPICER.—On Jan. 13th, overtaken by an avalanche, near Lenserheide, Switzerland, Dr. John Evan Spicer. aged 33 years, son of Mr. and Mrs. Evan Spicer, of Belair, Dulwich.

C

# HOMMEL'S Hæmatogen

CONTAINS NEITHER ALCOHOL NOR ANTISEPTICS

A combination of 80 parts purified and concentrated Hæmoglobin with 20 parts chemically pure Glycerine and Aromatic Flavouring.

The best of all the existing preparations of Hæmoglobin. More efficacious than Cod-Liver Oil or the ordinary manufactured preparations of Iron. Very strengthening both for Children and Adults. An energetic Blood Former. Increases the Appetite. Aids Digestion.

- Extremely useful in Rickets, Scrofula, General Debility, Anæmia. Weak Heart, Neurasthenia, and Convalescence from illness such as Pneumonia or Influenza.
- Unsurpassed as a Strengthening Restorative in Diseases of the Lungs. Has a very agreeable tastc, and is taken with the utmost relish even by Children.

FREE FROM BACTERIAL GROWTH. UNCHANGED BY KEEPING.

These important qualities are guaranteed by using the highest permissible temperature in the process of manufacture (130° to 140° Fahr. for 24 hours). No guarantee of this description is possible for preparations made by a cold process with ether.

In prescribing, always state "HOMMEL'S" Hæmatogen as spurious imitations are offered.

ONLY SUPPLIED IN FLUID, NOT IN CAPSULES OR OTHER FORMS.

Infants - Take from Half to One Teaspoonful twee a day in milk.

Children - One or Two Dessertspoonfuls daily, either pure or mixed with any convenient liquid.

One Tablespoonful 'wice a day before the two principal meals.

SAMPLES AND LITERATURE, gratis and carriage paid, on application.

NICOLAY & CO., 36 & 36a, ST. ANDREW'S HILL, LONDON, E.C.

AGENTS FOR NORTH AMERICA: LEHN & FINK, WILLIAM STREET, NEW YORK.

- "SCOTT'S Emulsion for incipient or threatening Consumption."
- "Bronchitis."
- "Taken with relish."

----, Manchester, March 20th, 1906.

"Dear Sirs,—I have recommended SCOTT'S EMULSION both for children and adults in cases of incipient or threatening consumption- I also find it good for children after they have been attacked by bronchitis following measles, severe colds, etc. I think the average child will take it with relish—a great point in the administration of any form of medicine to the young. I regard it as an elegantly prepared emulsion."

Faithfully Yours,

—— , M.D., Ch.B., F.R.G.S.

Late Ho. Surg. — Inf. & — Hosp.

16 cz B. ttie, with formula, free to any physician, surgeon, or certificated nurse desiring to test SCOTT'S EMULSION.

SOOTT & BOWNE, LTD., 10 and 11 Stonecutter Street, Ludgate Circus, London, E.C.

**EVIDENCE:** 

# The good effects of the bromides without concurrent disadvantages.

# **BROMETONE**

(tri-brom-tertiary-butyl-alcohol, the product of bromoform and acetone under the action of caustic alkalies) contains a higher percentage of bromine than does potassium bromide,

and will produce in much smaller doses sedative, hypnotic and analgesic effects fully equal to those of the alkaline bromides without exciting gastro-intestinal disturbance. Dose: 2 to 5 grains.

#### PHYSIOLOGICAL ACTION.

DRS. HOUGHTON and ALDRICH state: "The drug appears to have very little influence upon the heart or circulation, as shown by myocardiographic and blood-pressure tracings taken from curarised animals."—American Journal of Physiology, 1903.

PROFESSOR HARE reports: "The physiological action of Brometone is nearly identical with that of the older bromides. It is efficacious in small doses."—Practical Therapeutics.

#### PHYSICIANS' REPORTS.

#### Epilepsy.

W. Kempster, M.D., Emeritus Professor of Mental Diseases, Wisconsin College of Physicians, reports eight cases, some grand mal, some petit mal. "In all, the action of Brometone was prompt and characteristically sedative. In no case did it cause nausea or disturbance of the skin. The improvement in physique and mentality in all cases was marked."—Therapeutic Gazette, Feb., 1906.

W. P. SPRATLING, M.D., Superintendent Craig Colony for Epileptics, describes a case in which the face was one mass of sores from taking bromide for ten years. "I stopped the bromide and put him on Brometone. The effect was almost miraculous. In nine weeks, the skin cleared up, the eyes brightened, and the attacks dropped from 5 or 7 per month to 1 in three months."—New York State Journal of Medicine, Oct., 1906.

Dr. Joy, with an experience of over 50 years in the treatment of epilepsy, after prescribing Brometone where other treatment failed, states that its effects far exceeded his expectation, stopping the paroxysms almost at once and permitting discontinuance in four months or less.—Canadian Practitioner, June, 1907.

#### Headache, Neurotic Conditions, etc.

J. J. Kyle, M.D., writes: "In cases where we wish the nervous mechanism to receive rest and not be merely drugged into insensibility, Brometone seems to produce a condition similar to physiological rest, and its effects are not cumulative. It is well borne in the gastric irritation due to alcoholism, and is specially indicated in over-stimulation of the nerves by excessive brain work and in congestive headaches."—Medicine, Sept., 1904.

#### Insomnia, Chorea, etc.

In a series of 20 cases, Brometone proved an excellent sedative in mild excitement and insomnia, also in slight nervous affections of children and adults. In children aged six years, 2 grains thrice daily gave good results in chorea and epilepsy.—Medical and Surgical Monitor, June 15, 1904.

#### No ill-effects

H. ERICHSEN, M.D., reports the case of an epileptic, 44 years of age to whom Brometone was administered daily for more than a year without any indication of "bromism," and with improvement in physical and mental conditions.—Medical Age, Sept. 25, 1904.

Brometone is supplied in bottles of 1 ounce, also in capsules containing five grains, in bottles of 25 and 100.

## The

# Allenburys Foods

## Special Advantages:

- 1—The close conformity in composition of the Milk Foods to human milk; both fat and proteids being in similar relative proportions.
- 2—The readiness with which the Foods are assimilated; being as easy of digestion as maternal milk.
- 3—Their adaptability as an adjuvant to breast feeding during the period of weaning; no digestive troubles being likely to occur.
- 4—Their freedom from all harmful bacteria; being made from fresh milk, modified, evaporated at a low temperature, in vacuo, and preserved in hermetically sealed tins.
- 5—The ease and exactness with which the Foods can be prepared; the addition of hot water only being necessary.
- 6—Fresh elements of diet can be easily added to the Foods, and are specifically mentioned on each tin.

A reliable substitute is thus provided for the Mother's Milk, when this is wanting or deficient.

MILK FOOD No. 1.

MILK FOOD No. 2.

MALTED FOOD No. 3.

## Notes and Comments.

THE exclusion from most London and The English many provincial hospital posts of all Colleges and but holders of the Fellowship of the Hospital Posts. English College of Surgeons, or the Membership or Fellowship of the London College of Physicians, is a grievance of old standing. It has been brought once again into the field of medical politics by the conjoint forces of the Irish Graduates' and Schools' and the Scottish Medical Diplomates' Associations. The meetings held last week in London were restricted to the medical profession, but the matter is clearly one that will have to be settled by the governors of hospitals, and possibly by Parliament. It is extremely unlikely that the English Colleges will stir a finger towards a reform which will disturb the nice little monopoly which they now enjoy. On the other hand, the governors make and unmake hospital laws, and it is only right that their attenrion should be drawn to a condition whereby, so it is alleged, many good candidates are excluded from

The Arguments.

competition.

Most of the arguments are on the side of those who object to the exclusion, and that is natural enough, for it is not the way of monopolists

to argue-they simply sit tight and listen in silence. One point likely to impress lay governors is the fact that a large number of successful Scotch and Irish graduates, not to mention members and associates of the English Colleges and holders of other excluded degrees and dip-lomas, are engaged in private practice. They are, therefore, good enough to attend the hospital governors, but not sufficiently well educated to attend hospital patients. Let the governors reflect before they issue any more advertisements for candidates with an English college higher diploma; they are simply proclaiming to the world the inferiority of the private medical attendants of a large section of the community. We are glad to learn that University College has joined several other large Hospitals in throwing open the staff appointments. That, at any rate, is a logical inference, however remote it may be from the minds of those who advertise such posts in the Times and other daily journals.

WHAT do the English Colleges What is give in return for this monopoly? So far as can be seen on the surface, they take all they can the "Quid pro Quo? " get and give absolutely nothing in return. The hospital posts are divided between the Fellows of the Surgeons' and Members and Fellows of the Physicians' Colleges. So finely woven are the meshes of the monopoly that members of the Royal College of Surgeons and licentiates of the Royal College of Physicians are

left out in the cold with all the rest of the qualifying degrees and diplomas. It is to be hoped that the matter will always be discussed in a temperate and reasonable spirit. Several distinguished Irishmen were present at the London meeting, notably Sir Charles Ball and the Presidents of the Irish Colleges of Surgeons and Physicians, Mr. Lentaigne, and Dr. Horne. It is much to be regretted that none of the leading Scotch college men were represented at a movement in which the interests of their diplomates are so closely concerned. Professor Glaister, President of the Faculty of Physicians and Surgeons of Glasgow, was, unfortunately, prevented at the last moment from attending. We shall await with interest the further action of the conjoint Scotch and Irish committee.

A "Beauty Specialist."

News comes from America of the death of a Dr. Woodbury, who is said to be the pioneer of "beauty specialists." The unfortunate man, who had amassed a large fortune,

committed suicide, so that it is invidious to criticise him or his cult. We do not know how far he was regarded as an orthodox practitioner in America, where such wide laxity in medical ethics prevails, but as he advertised in all the New York trams and ran a "Facial Culture Company," he was what would be regarded here as the most objectionable type of quack, namely, the renegade doctor. A side of the charlatan's life which the general public, and even the medical profession, as such, hear but little of, is that which deals with failure, and though Woodbury was successful in some of his treatments, his failures were many and serious. Disappointed ladies assaulted him, alleging that their appearance was ruined for life, and legal actions for damages were several times brought against him. Yet the game went on and the money rolled in, for only a few days before his death he paid as much as £10,000 for a piece of property. One is tempted to draw from this career at least one lesson, namely, that the type of man who is a successful charlatan is the "bluffer," the man of unlimited self-assurance and power of throwing dust in the eyes of others, but that there is generally a limit to the powers of keeping the deception up. and when that point is reached, ruin or shame or disgust crush a spirit which seemed proof to all impressions. Under such circumstances self-destruction is the natural corollary.

JUDGE WILLIS is certainly supersed-Hoar-Frost ing Mr. Plowden as the licensed joker of the Bench; at any rate, he for the Complexion. is being boomed by the press in that capacity, and Mr. Plowden is hardly ever quoted now. We cannot say that the jests which he is reported as making are of the side-

splitting variety; indeed, they seem to belong rather to the senile order, but they are duly chronicled by obsequious journals as if they were the utterances of a very Sydney Smith. An adjourned case was before His Honour last week, in which a firm of druggists sued a "Dr. Paget, of Oxford Street, in respect of a quantity of ointment called "hoar-frost," which had been supplied to him to sell to ladies as an application for the complexion. At the previous hearing much merriment of the judicial order—had been made over the use of the stuff, and over the alleged fact that the hoar-frost turned into a chalky substance when the box containing it was left open. In the result the defendant lost the case and had to pay, but the fact that interests us is, that a gentleman holding the position of a judge should think that it is part of a medical man's business to trade in face-creams and such preparations for the complexion. Needless to say, there is no "Dr. Paget of Oxford Street" on the Medical Register, and at whatever university he may have laboriously succeeded in graduating, it is not one recognised by the General Medical Council. It is no more part of a medical man's practice to sell face-creams than it is of a barrister's.

THE Birmingham Vegetarian Society One Acre had the rich treat last week of enjoyand ing addresses from one Dr. George a Cabbage. Black and a Mrs. Cobden-Saunderson, who boasted that she had known the inside of one of H.M.'s gaols for disorderly conduct as a suffragette. In their hands the gospel of green food was exalted to a pitch so giddy that one cannot be surprised that its equilibrium was unstable. Dr. Black was armed with figures in regard to infantile mortality and kindred subjects that made the flesh creep, and, needless to say, that the nasty habit of eating meat was largely responsible for these disasters. Saunderson took the question a stage further by placing it on an ethical level, though she was "not blind to the inconsistency of the vegetarian who condemned the slaughter of animals for meat, yet wore boots, shoes, and gloves, and ate cheese into which rennet entered." Certainly, when one dives into these subjects, with the ethical notion alone to guide one, some very odd and inconvenient consequences are encountered. The lecturer proceeded to show the eating of fruit would reduce crime—or, rather, to assert that it would, for we rather fear it might conduce to cannibalism-and bring ruin to brewers. The peroration soared into a perfervid sphere, and denounced three acres and a cow as the final apotheosis of man. What was wanted, she said, was one acre and intensive culture! And at that we may well leave it.

Reward for First Aid.

THE men and women who give up a considerable portion of their time to study first aid do so, as a rule, with the entirely unselfish desire of benefiting their fellow-creatures, and it is

certain that if they looked for fee or reward for their efforts they would find themselves almost uniformly disappointed. It is all the more satisfactory, then, to be able to record that in the case of one man who by his knowledge of ambulance work, was instrumental in saving a fellow-workmen's life, has been rewarded. The incident occurred at the Tredegar Company's power-house at Pochin Colliery, some two months ago, a workman coming into contact with a live wire and being nearly electrocuted. Fortunately a man named Joseph Marsden was at hand, and by performing artificial respiration he

was able to restore the patient, and in recognition of this act his fellow-workmen subscribed and presented him with a gold medal. When the small amount of practical good done by the ambulance classes held throughout the land is commented on, it is well to record incidents of this kind, and of their appreciation by those most immediately concerned.

#### LEADING ARTICLES.

MONOPOLY AND HOSPITAL APPOINT-MENTS.

Last week a conjoint meeting of the Irish Medical Schools' and Graduates' and the Scottish Medical Diplomates' Associations was held in London. The object was to discuss the old-standing grievance of the exclusion of the holders of Scotch and Irish qualifications from most of the important London and many of the provincial hospital appointments by making the possession of a higher diploma of one of the London Royal Colleges an indispensable condition of tenure. The result is to confer a valuable monopoly upon the Fellows of the Royal College of Surgeons of England and the Members and Fellows of the Royal College of Physicians of London. It should be carefully noted that so cribbed and strictly defined is this monopoly that it actually excludes the members of the College of Surgeons and the licentiates of the College of Physicians, not to mention graduates in medicine and surgery of London and provincial Universities. The practice referred to doubtless began in times when, in England, at any rate, the two English Colleges held the field. Its survival into present times, however, constitutes an anachronism of a peculiar and, in many ways, a most objectionable nature. Nowadays there are a number of excellent medical schools scattered throughout the United Kingdom where students can obtain a first-rate education, and qualify subsequently at British Universities, or at one of the Scotch or Irish corporations. These gentlemen, although holders of a State qualification, will, for the most part, find themselves debarred in later life from a chance of holding hospital posts that are admittedly essential to the attainment of a high standard of excellence in professional life. Clearly, their exclusion is an excellent thing for the English Colleges, inasmuch as it gives their alumni the practical monopoly of the important hospital posts in England, and compels many holders of provincial qualifications to take their diploma simply and solely for the purpose of opening the door to a desirable appointment. It is hardly likely that the English Colleges will take any steps towards putting an end to a state of affairs so favourable to their own interests. The matter is one for the medical profession generally, for the lay public and the State to inquire into and, if necessary, to remedy. So far as the medical profession are concerned, their verdict has been unanimous in condemnation of the exclusion of certain qualifications from hospital appointments. The medical journals agree also. The British Medical Association has emphatically recorded its disapproval on several occasions. The Irish Graduates' and Schools' Association has been fighting the injustice for the last twenty years, and is now joined by the Scottish Medical Diplomates'

Association. Various provincial hospitals, on being fully informed of this invidious condition, have thrown open the posts to all comers. The Lords' Committee of Inquiry into the London hospitals advocated the open door to all qualifications. short, wherever an appeal has been made to any authoritative public body, professional or otherwise, the favoured college clause has been invariably condemned. The English Colleges will probably attempt to evade the issue by saying the exclusion is none of their doing, but rests with the governors, who make the rules of the hospitals. That is true so far as the legal responsibility is concerned, and the matter will have to be referred eventually to the public for settlement. Meanwhile, the united Scotch and Irish Associations have very wisely opened the campaign by a calm and dignified appeal to the exercise of justice and fair play of their professional brethren. When the matter is clearly placed before the public there can be little fear as to the ultimate verdict that will be given. existence of a class monopoly of the kind is hopelessly out of touch with the democratic spirit of modern times; and so, too, for that matter, is the antiquated and irresponsible government of the qualifying corporations. The question of preferential privileges to certain licensing bodies, indeed, forms one of various anomalies that sooner or later will have to be dealt with by the State in the interests of the community. Were the General Medical Council constituted on a representative and business-like basis, a class privilege of this kind would receive prompt attention. It is to be hoped that the conjoint Irish and Scotch Associations will induce the British Medical Association to take up vigorously this vexed question of monopoly in hospital appointments.

#### CURRENT TOPICS.

#### Compulsory Irish.

THE war over the question of compulsory Irish in the new National University goes on gaily in the columns of the daily papers, and it appears likely that it will go on in spite of the fact that the Catholic Hierarchy has issued a statement, in which they point out the inadvisability of compulsion at present. From a medical point of view the question is interesting, first, because it has been seriously suggested that a knowledge of Irish is of more value to the average medical man than a knowledge of French and German; and, secondly, because it is suggested that the University should not accept any substitute for their own matriculation examination, because to do so would enable candidates to enter without showing their knowledge of Irish. Again, at the back of all, and apart from the actual question as to whether or not Irish should be compulsory, is the knowledge that, if the University authorities once yield to popular clamour, their independence and their power of academic action is gone for ever. At present, the position to the outsider resembles a deadlock, as whichever party gets its way it seems as if the result would be disastrous to the University. It will be hoped the Senate will from the beginning show strongly that it is not to be influenced by clamour, and that the Irish-speaking party will consent to waive their

sentiments out of regard for the material interests of their country.

A "Pampered" Medical School.
Under the heading, "Pampered Medical Schools," a contemporary, which delights to pour contempt on medical men and medical work, records the donation to the School of the London Hospital of £20,000 to endow medical research. As the medical schools of the London hospitals are practically unendowed, and as most of them can hardly make two ends meet, without applying any money to encourage original research, the fact that one of them receives £20,000 for the highest purposes that mankind can pursue, hardly supplies the justification that the schools are "pampered." We most gratefully acknowledge the noble disinterestedness of the donor, who not only wishes to remain anonymousand therefore is not a candidate for New Year or Birthday honours—but has given the money during his lifetime, and so made a personal sacrifice. But, knowing the pressing need for the extension of scientific knowledge about disease and diseaseprocesses, medical men cannot but wonder that the rich and philanthropic give, and even give generously, to objects which relieve suffering, and yet hardly open their purses to subsidise the prevention of suffering. No doubt we have to thank the antivivisectionists largely for this perverted idea of humanitarianism, and if it gives them pleasure to know that they are the cause of much of the most poignant misery in the world, they may take what comfort they like out of the reflection. Hospitals, after all, only deal with the results of evils, and it will not be till we know, and can remove, the causes that produce those evils, how they can be recognised in their earliest stages, and how nipped in the bud, that substantial progress will be made in promoting the welfare of mankind. Till the ground is cleared and facilities are granted for abundant organised research into these factors, we are frequently only administering pills for earthquakes. All the more honour, then, to the noble-hearted and clear-minded gentlemen who, like the anonymous benefactor of the London Hospital, brave the snarls of the antihumanitarian and give their money to this great cause.

#### Wrong Medicine.

WE confess to considerable sympathy with a nurse who gives a wrong dose of medicine to a patient in hospital, as it is obvious that, while human nature remains as frail as it is, such mistakes will occasionally occur, and whereas in most other callings a similar error would do little or no harm, in that of a nurse the consequences are apt to be most serious. Indeed, the only person with whom we have more sympathy is the unfortunate patient, who, looking on the nurse as his trustee, takes what she gives him with confidence. An occurrence of the kind took place at an asylum quite recently in which a senior nurse, before going off duty, seems to have instructed her subordinate to give patients their medicines according to colour-dark red to so-and-so, light red to so-and-so, and green to a third. At the inquest which followed, the Coroner remarked that this was a happy-go-lucky method of doing things, and we cannot say the epithet erred on the side of harshness. The patient actually died of chronic bronchitis, and the medical man in charge was able to say that he was satisfied that the administration of 1½ grains of morphia, which the patient had actually received, had in no way accelerated death. The Coroner, in censuring the head-nurse, said that it was "lucky" for her that death had not been caused by the mistake; and, indeed, it was. But the most incomprehensible part of the affair is, what would have happened to the right patient if he had had 1½ grains of morphia administered to him?

The "Property Doctor."

A CORRESPONDENT writes us to protest against the way in which the medical practitioner is handled in fiction. He is treated, says our protestant, like the lay figure in an artist's studio, in the sense that he is arbitrarily placed in a certain-possibly ridiculous, or, at any rate, improbable-attitude, and is left there until altered circumstances necessitate modification. In accordance with the requirements of the plot, he is represented as preternaturally sagacious and prophetic, albeit exceedingly indiscreet, or he is roughly delineated as a blundering fool. Feminine authors, it must be conceded, usually deal tenderly with the family doctor, whom they endeavour to render sympathetic, though in the process he is apt to become a trifle stodgy, not to say Mrs. Gampy. Or, circumstances permitting, we are treated to the type of the "ladies' doctor," a being quite apart, who pats duchesses on the cheek with a familiarity begotten of intellectual superiority, and associates a sort of Sherlock Holmes' insight in the matter of diagnosis with the (supposed) manners of a man of the world, blase by much success. Male authors are much less scrupulous; they smack the doctor on the back, à la Hall Caine, and, with unwarrantable familiarity, make him utter opinions and volunteer advice with a regrettable lack of logic and discretion. worst offender, however, is the pseudo-medical writer, he who somehow or another has lived in actual contact with medical oracles. In French literature he is simply unutterable, whether he credits the practitioner with a prescience unknown in practice, or, on the contrary, triumphantly emphasises his least pardonable weaknesses, à la Leon Daudet. Pathology in fiction is fearfully and wonderfully made, for the symptoms are stricken with incoherence and accorded unauthorised significance. Patients display the most disconcerting alternations of delirium and perspicacity; they are dying one minute and are abominably active the next; in fact, there is a lamentable uniformity of morbid conditions. After all, the most tiresome literary products are those in which none of these faults is committed, novels in which every symptom is accurately described at great length, along with the treatment, and the doctor, by his prolixity, is depicted as an insufferable bore.

Dirty Dublin.

WHEN, last winter, we had occasion to call attention to the inadequate manner in which street-cleansing in Dublin is performed, we were speedily brought to book in the Dublin Corporation on the initiative of a medical member, who had our remarks referred to the Cleansing Committee for report. We regret to note that this winter matters

are in even a worse condition than heretofore. The streets are left ankle deep in mud, and when the winds of March come, we may look for even more than the usual supply of street dust and horse manure to be whirled into bedroom windows. Incidentally, we may mention that we are glad to find our critic of last year calling attention in the papers to the present scandalous condition of affairs. As regards the public health, Dublin has had a peculiarly bad year, culminating a week or two ago in a mortality rate of 29 per 1,000. There has been an epidemic of typhoid which the health authorities were unable to explain, although it is not improbable that some of the misplaced activities of the Corporation were responsible for it. Moreover, apart from this epidemic, which was limited to one district, the incidence of the disease through the city generally has been heavier than for some years back. It is not reassuring, therefore, to find that the municipal authorities are as careless as ever with regard to their duty of cleansing the streets.

Mortality among Medical Men.

According to its custom, our contemporary, The Journal of the American Medical Association, has, in its first issue for the new year, analysed the deaths of medical men recorded in its columns during the past twelve months. The total number of deaths of medical men in the United States and Canada, recorded during the year, was 2,261, which gives a mortality rate of 17.39 per 1,000. The age at death varied from 21 to 102 years, the average being 59½. The number of years in practice varied from less than one to seventy-six, the average being thirty. Chief among the causes of death were heart disease, violence, pneumonia, and cerebral hæmorrhage. The number of deaths from violence seems very high-175, including 126 from accidents, 34 from suicide, and 12 from homicide. Of the 126 acidents, 7 were motor casualties. Of the 34 suicides, 20 were due to gunshot wounds, 6 to poison, 3 to cutting instruments, 2 to asphyxiation, and I each to falling, drowning, and strangulation. It is curious that among medical men, who might be presumed to be acquainted with the action of, and to have facility in obtaining, the more painless and easy poisons, shooting should be the favourite means of self-destruction. All the homicides were due to gunshot wounds, and four of these occurred in duels or feuds. The Journal recorded the deaths of several distinguished men during the year, the chief being Nicholas Senn of Chicago, and Roosa and Edebohls of New York.

Expert Evidence.

In a case for damages arising out of a motor smash, heard last week in Dublin, counsel for the defence varied the old plan of abusing the plaintiff's attorney, and instead abused the expert witnesses. Without following him in his criticism in the particular case—criticism, of course, to be regarded merely as advocacy—we confess that the condition as regards expert evidence is one not wholly calculated to support the dignity of the medical profession. It is the custom in every case for damages for injury to produce two or three experts who swear that in their opinion the plaintiff is suffering from injuries of one kind or another of

a certain character. On the other side, equally eminent experts are produced to swear to another view of the alleged injuries. It is really difficult to believe in the bona fides of all the opinions expressed under such circumstances, and, as a matter of fact, evidence is sometimes given so absurd that it can have little effect except on the ignorant juries. On the other hand, many of those who give evidence in these cases are men of acknowledged authority in the profession. Of course, we are not to be taken as in any way reflecting on members of the profession who give expression to their honest opinions in the witnessbox, but there is cause for reflection in what that astute lawyer. Lord Chief Baron Palles, remarked the other day, that he was more influenced by the evidence of medical men in actual attendance on a patient than by that of half a dozen experts.

#### Vermin and Disease.

In the fight against disease no agency which is of service should be neglected. Those that are not against us are for us, and should be enlisted as allies. We confess that we are somewhat inclined to look askance at the Incorporated Society for the Destruction of Vermin, for, while wholly sympathetic with its objects, we do not see quite how their desiderata are to be accomplished. Even the poorest are ashamed of being vermin-laden, and they will strenuously argue that an accuser is mistaken as to his facts, even when the evidence is palpable to the most astigmatic eye. It is not, then, a question of education, such, for instance, as is needed with regard to infectiveness of tuberculosis. Nor can that Mesopotamian panacea, notification, accomplish much, for it is not likely that the legislature would make the notification of bug-bites compulsory, or even permissive. Nor, again, can it be hoped that the law will allow the harbourer of fleas to be marched off by the police for fumigation. In a free country everyone is entitled to enjoy his own coating of dirt so long as he pays his water-rate. Still, the Society for the Destruction of Vermin, so long as it does not draw down too much ridicule from the cavillers at modern manners, may accomplish something in the way of eradicating a fruitful source of disease, and, while we wish them all success, we may say that we fear their path will not be an easy one. It will be difficult to get packed and enthusiastic meetings to support a cause so little appealing to the imagination; leaflets and manifestoes kill no vermin; and there will always be scoffers.

#### PERSONAL.

H.R.H. THE PRINCESS OF WALES has intimated her intention of visiting the Great Northern Central Hospital on Monday, February 22nd, in the afternoon, to open the new ward for children provided through funds collected by the Ladies' Association, of which her Royal Highness is the President.

The Duchess of Albany presided at a meeting of the Executive Committee of the Jubilee Fund of the National Hospital for the Paralysed and Epileptic, Queen Square, Bloomsbury, on January 18th. It was announced that over £11,000 had been collected and promised towards the £50,000 for which the Duchess is appealing, including a donation of £1,000 from Lord Strathcona, the President of the hospital.

- Dr. T. M. Allison has been appointed Honorary Assistant Physician to the Royal Victoria Infirmary, Newcastle-on-Tyne.
- Dr. Phineas Abraham has resigned his post of Surgeon to the Hospital for Diseases of the Skin, Stamford Street, Blackfriars.
- SIR FREDERICK TREVES, Bart., delivered a lecture on "Radium in Surgery" at the London Hospital Medical College, on Tuesday, January 26th.
- Dr. E. F. MACLEOD NEAVE has been elected to the post of Medical Inspector of School Children under Manchester Education Committee.
- LORD DERBY, the President, on January 16th, laid the foundation-stone of a new Liverpool Dental Hospital, which is to be erected on the site near the University and the Royal Infirmary.
- DR. ROBERT JONES has been elected to succeed Dr. T. Claye Shaw as Lecturer on Mental Diseases at St. Bartholomew's Hospital. He has consequently resigned his post at the Westminster Hospital Medical School.

THE Festival Dinner of the Hampstead General Hospital (with which is amalgamated the North-West London Hospital) will be held at the Trocadero Restaurant on February 16th. The chairman is Mr. Samuel Figgis.

AT a meeting of the Royal Statistical Society, held on January 19th, a paper was read, entitled "The Cost, Conditions, and Results of Hospital Relief in London" (Howard Medal Prize Essay), by Mr. Percy E. Braun, B.Sc.

SIR ALFRED JONES, K.C.M.G., as Chairman of the Liverpool School of Tropical Medicine, which he founded, delivered his Inaugural Address to the students on Monday on the subject of "The Practical Importance of the Study of Tropical Medicine."

THE three Morison Lectures of the Royal College of Physicians of Edinburgh are being given in the College Hall by Dr. F. W. Mott, F.R.S., this week, the subject being "Syphilis of the Nervous System in the Light of Modern Research."

DR. CHARLES MERCIER has been awarded the Swiney Prize by the Royal Society of Arts for his work on "Criminal Responsibility." The prize is a cup of the value of £100 and money to the same amount, the award being made jointly by the Royal Society of Arts and the Royal College of Physicians of London.

Dr. J. J. Charles, M.D., D.Sc., F.R.S.E., formerly Professor of Anatomy and Physiology in Cork University College, has presented an engraved die, and a sum of money sufficient to provide an annual gold medal, to be given alternately in the subjects of which Dr. Charles was professor. The governing body have accepted this offer, and ordered that the medal shall be called the "Charles Medal."

THE Council of the Sheffield University on January 18th considered a report, prepared by the Vice-Chancellor, on the application of the increased income which will accrue to the University under the will of the late Dr. Hunter, of Bath, who left the institution £15,000. In accordance with the terms of the late Dr. Hunter's will the name of his father, Joseph Hunter, has to be associated with the fund.

THE German Urological Society will hold its second Congress at Berlin, April 18th to 22nd, 1909. Among the subjects to be discussed are suppurative nontuberculous affections of the kidneys and tumours of the bladder.

## A CLINICAL LECTURE

ON

## THE PERONEAL TYPE OF MUSCULAR ATROPHY. (a).

By ARTHUR WHITING, M.D.Edin., M.R.C.P.Lond.,

Physician to the Prince of Wales's General Hospital, N.; Assistant I hysician to the Mount Vernon Hospital for Consumption and other Diseases of the Chest; Lecturer in, and Dean of, the North-East London Post-Graduate College.

Gentlemen,—We have at various times discussed together different examples of familial disease, such as hæmophilia, angioneurotic ædema, Friedreich's ataxia, and pseudo-hypertrophic paralysis with other myopathies. The subject for our consideration this afternoon is another familial disease; it is also a form of muscular atrophy, but it is not, as we shall see, a myopathy. The muscular atrophies which are not primarily muscular are due, as you know, either to disease of the anterior horn cells of the spinal cord—as anterior poliomyelitis, which may be said to be a massive lesion, and progressive muscular atrophy, which may be said to be due to a cellular lesion—or to disease of the nerve fibres between these cells and the muscle fibres, whether in the anterior roots, the nerve plexuses, the nerve trunks, or the peripheral intra-muscular terminations of the motor nerves. The peroneal type of muscular atrophy, as we shall see, is associated with pathological changes, both in the spinal cord and in the peripheral nerve trunks.

It is called "peroneal" because it seems to start in the muscles below the knee, possibly really in the peronei. It is sometimes said to be a special type of "progressive muscular atrophy," but it is quite unlike that disease; among other things, it begins in the legs, not in the hands; it occurs in early and not adult life, and it is hereditary.

The three patients who have come to hospital this afternoon for the purpose of this demonstration are a middle-aged man and his two daughters, who have been under Dr. J. R. Halliday's observation and my own for several years. The man's mother and brother had the disease, as also had his maternal grandfather. I do not propose to give you now all the clinical details of these cases; those Dr. Halliday and I hope to publish together shortly, but the following is an abstract of their case-records:—

The first patient, the father of the other two, a cardboard cutter by occupation, is forty-four years of age, has suffered from paralysis followed by clubbing of his feet since he was eight, and from paralysis followed by clawing of the hands since he was thirty-two years of age. The hereditary history is as follows:—His mother, whose family consisted of the patient and his brother, developed clubbing of the feet at the age of seventeen; her father had deformity of the feet; of her two sons, the younger brother of the patient developed clubbing of the feet at seventeen, and clawing of the hands between the twentieth and twenty-fifth years. Patient's younger daughter showed a tendency to club-foot at ten, and weakness of the hands at eleven, and an elder daughter is now obviously developing the condition. He was healthy up to the age of eight, when he had measles, and shortly afterwards the condition from which he is now suffering began to develop. He has always been temperate, and has never had any venereal disease. A few

months after recovering from the attack of measles. he began to walk on the outer edge of his feet, and some seven years later he underwent an orthopædic operation for club feet. The condition remained stationary until thirty-two, when the weakness of his legs increased, his hands began to be weak and he was unable to feel things in the dark so well as before; during the next few years he developed some ataxy in walking and standing, so that he fell into the basin when he washed his face; he had shooting pains in the legs at intervals, girdle sensation and perfection when the washed her bett for tion, and perforating ulcer developed on both feet. It may be said here that his brother also suffered from perforating ulcer of the feet. His present. condition is as follows:-He is a pale, obese man with a rather expressionless face; there is double club-foot with claw toe; inability to abduct or ad-duct the feet or extend the toes; wasting of the muscles below the knees, especially of the peroneal group, with modified reaction of degeneration in the wasted muscles; absence of the knee-jerks; coldness with pigmentation and glossiness of the skin of the legs, and sock anæsthesia to touch, pain, and temperature. There is double claw hand, with marked wasting of the thenar, hypothenar, and interosseous muscles, and slight wasting of those of the forearms with similar electrical changes. There is glove anæsthesia to all forms, but no ulnar anæsthesia. There is some ataxy of both legs and arms, Romberg's sign, small un-equal pupils showing the Argyll-Robertson phenomenon, and a persistent open perforating ulcer on the right foot, and the scar of a healed one on the left. He has had no sphincter trouble, and the optic discs are healthy. There are fibrillary tremors in the intrinsic muscles of both hands, and lateral curvature of the spine, with convexity to the right. The body organs are healthy. Careful search revealed no evidence of any thickening of the peripheral nerves.

Case 2.—The second case is that of the younger daughter of the patient just described. She is sixteen years of age. She had whooping-cough when three years old, but remained apparently healthy until the age of ten, living an ordinary active life of childhood. Shortly after she was ten she began to walk on the sides of her feet, and about a year later weakness of her hands was noticed.

Her state, on examination, was that the muscles of the legs below the knees were wasted; when lying down or sitting with the legs dangling she showed double drop-foot, and there was slight talipes varus, with some pes cavus. She could not dorsiflex the right foot at all, and the left foot only very feebly, and she could not stand on tip-toe. The knee-jerks could not be obtained even with any method of reinforcement. There was some anæsthesia of the feet, especially about the soles. There was no obvious atrophy in the upper limbs, but that the weakness was considerable and progressing was shown by the fact that whereas a few months before (I am now quoting Dr. Halliday's notes) she was able to open the spring of a neck fur with-

<sup>(</sup>a) Delivered at the North-East London Post-Graduate College (Prince of Wales's General Hospital, N.), on November 26th, 1908.

her hand, she was now unable to do so, and used her teeth for the purpose. There was lateral curvature of the spine with the convexity to the right. The electrical examination was difficult owing to the patient's nervous state, but the general result was that there was a marked diminution of faradic excitability. There was no ataxy, and the pupils gave normal reactions.

Since these notes were taken the girl has been increasing rapidly in height and weight, her legs now drag in walking, the big toes turn up, she wears away the soles of her boots on the inner side before the rest, and her hands have become splaw-like, so that she has to use her whole hand (or the fingers alone) when she takes off her boots

or other clothing.

Case 3.—I do not intend to trouble you much with details of the case of the elder sister. I shall merely say that she is apparently just beginning to follow the course of her younger sister. There is weakness and some wasting of the muscles on the outer side of the legs below the knees, and the knee-jerks cannot be obtained even with reinforcement. The electrical reactions have not been taken mainly because the patient has a rooted objection to that method of examination.

Neither do I intend to trouble you with details of the earlier cases in the family, merely saying that the only brother of Case 1, the uncle of Cases 2 and 3, developed clubbing of the feet at sixteen, clawing of the hands about twenty-two, and perforating ulcers in both feet about the same time, for which the right foot was amoutated when he

was twenty-three.

The mother of the first patient developed clubbing of the feet at seventeen; she married at thirty-five and had only two children—the two sons already referred to. She could play the piano up to shortly before her death, which occurred at fifty from heart disease, so her hands were, presumably, unaffected.

Her father, the great-grandfather of the two younger patients here this afternoon, suffered from some deformity of both feet, which may probably be safely assumed to have been the family clubbing.

This family group of cases affords instances of the peroneal type of muscular atrophy, the more exact knowledge of which symptom-complex dates from 1886, when Dr. Howard Tooth in this country, and MM. Charcot and Marie in France, clearly differentiated it from progressive muscular atrophy of myelopathic origin on the one hand, and from primary myopathies on the other. But about ten years before that, Leyden and others had pointed out that those cases of progressive atrophy which did not begin in the hands as in the Aran-Duchenne type, but in the feet were often here-ditary.

The atrophy and weakness usually manifest themselves in childhood, and, it is alleged, first of all in the peronei, but it is a question whether the onset is not, often, at least, first in the intrinsic muscles of the feet, a position in which the effects of weakness would not soon be obvious. Then the atrophy attacks the tibialis anticus, the long flexors of the digits, and, later, the calf muscles. There develops a talipes varus, and usually claw toe as well. Next the thigh muscles are affected, particularly the lower thigh muscles, and of these the vastus internus especially. Next, after a greatly varying interval, as our cases show, the intrinsic muscles of the hands are affected, giving claw hands; indeed, it may be said that this is about the only disease in which claw hand does appear in early life. Later still, the forearms and upper

arms are affected, and the wasting may indeed become general. The knee-jerks are absent in the developed case; there is usually patchy anæsthesia of the hands and feet and legs, but there is, as a

rule, no sphincter trouble.

The electrical reaction may be said, I think, to be characteristic. As a general statement, it may be said that there is reaction of degeneration—somewhat modified, perhaps—in the wasted muscles, but the remarkable thing is that there is greatly diminished excitability to faradism, even in the muscles that are not wasted or obviously weak, and at the same time the sensibility to faradic stimulation of the skin is greatly reduced. To galvanism a contraction was obtained in my own muscle with 2.75 milliampères. No contraction in the biceps of the patient (not specially atrophied), and only a very doubtful one in the interossei was obtained with a current of 20 milliampères. I may say that there was no appreciable atrophy of this man's facial muscles, but his face was distinctly expressionless.

These cases, then, correspond with the describer type in their hereditary tendency, in the onset it early life after an acute specific fever (in the father of the two girls, as has often been the case in other patients, after measles), in the double club-foot and double claw hand, with anæsthesia and characteristic electrical phenomena, both in the muscles that were obviously wasted and in those

that were not.

The unusual features of the first case are those that suggest tabes dorsalis, to wit, together with the absent knee-jerks and patchy anæsthesia, the ataxy, the shooting pains, the Argyll-Robertson pupil, and the perforating ulcers of the feet. But this case is by no means unique in its manifestations of tabetic signs. It may, however, be well to remark that, after most careful examination and consideration, the previous occurrence of specific disease was excluded from this patient. Without troubling you with names of authorities or precise references, I may say that by several observers lightning pains have been recorded in similar cases, also by one, at least, the Argyll-Robertson pupil, in others optic atrophy, in some myosis, and in a few difficulties with urination, and in even one-I had thought Dr. Halliday's were unique-perforating ulcer.

To summarise the pathological findings of the more recent investigations, several have found degeneration of peripheral nerves, muscles, and posterior columns of the cord; some have found lesions both of the posterior horns and the anterior horns, and a few have observed a hypertrophy of the interstitial substance of the nerves. I may remind you that muscular atrophy is by no means unknown in unequivocal cases of tabes dorsalis.

In reference to the question of sex-frequency, it is usually said that males are more frequently affected than females as five to one, but in the present family that does not appear to be the case; indeed, the heredity seems to follow the rule in certain other nervous disorders of transmission from the mother to the son, and the father to the

daughter.

In reference to ætiology, it is clear that there is an inherited vulnerability, to say the least, of nearly the whole of the lower nervous system, and, indeed, possibly also of the higher, as an erratic, bizarre, excitable psychology is held by some to be characteristic of the disease. In this respect it seems very closely to resemble Friedriech's hereditary ataxia.

In addition to this predisposing cause, there is clear evidence that in many cases there is also an exciting cause, usually in the form of some acute

specific fever, particularly, as the case-records seem to suggest, measles; but other toxic agents, as alcohol and lead, have been held to participate, and even conditions of muscular and mental stress have seemed to have had a share in the development of

Up to the present, effective treatment may be summed up in almost a word, namely, well-directed tenotomies; any other is of but little, if any, avail.

Note.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Professor A. Dietrich, M.D., Prosector at the Krankenhaus, Westend, Charlottenburg Berlin. Subject: "Simultaneous Existence of Congenital and Acquired Disease of the Heart."

#### ORIGINAL PAPERS.

#### CASE OF INCONTINENCE OF URINE ASSOCIATED WITH EPISPADIAS.

By R. P. ROWLANDS, M.S., F.R.C.S., Assistant Surgeon to Guy's Hospital.

A BOY, æt. 6, was sent to me early in June, 1908, by Dr. B. A. Richmond, of Bermondsey, for incontinence of urine associated with epispadias. He was able to retain the urine fairly well while lving down at night, but directly he either stood or sat up it ran away. Throughout the day the water dripped into the clothes, keeping the trousers constantly wet and rotting them in a short time. Dr. Richmond wrote that "complaints were made at school that the boy was undesirable, because his clothes smelt so strongly. I hope that you will be able to recommend something to relieve a very distressing condition. The question is, can any plastic operation be done?'

In other respects the boy was well developed, except that the right testicle was retained in the inguinal region, and that the symphysis pubis was depressed and thin. The penis was so extremely small, that only a little bud presented below the arched lower border of the pubic skin. The epispadias was nearly complete, but the cleft did not extend quite into the bladder, the posterior inch of the urethra being roofed over with mucous membrane only.

Diagnosis.—It was obvious that the bladder was of fair size, because it was capable of holding all the urine secreted during the night, if the body lay horizontal. The complete incontinence in the vertical position proved that there could be no sphincteric control. Gravity, atmospheric pressure and the apposition of the mucous walls of the urethra were usually sufficient to prevent leakage while the trunk remained flat and the muscles at rest. It was concluded, therefore, that although the cleft did not extend into the bladder, the sphincter had failed to meet in front of the urethra, and the neck of the bladder. It was hoped that some of the muscle fibres existed, but that they were powerless, because they had not been able to complete the circle that is necessary for control.

Treatment.—In considering the treatment of this boy it was clear that it would be almost impossible to fit him with a urinal that would both keep him dry and make him "desirable" at school. The sickening odour of stale urine would still make him an unpleasant companion, and the object of derision, for even the best cleaned urinal smells. It seemed to me that it was worth while for this boy to run a considerable risk in order to be rid of his incontinence, and to be saved from a pestilent urinal as a permanent necessity. I therefore recommended an operation, although the chances of complete success did not seem to be good. If the operation should fail a urinal could be used, or the urine could be diverted into the rectum in one way or another. In a few cases of epispadias with extension of the cleft through the neck of the bladder, Trendelenburg had been able to construct a moderate sphincter by carefully suturing the freshened and liberated edges of the cleft. This has only been possible after mobilising the sacro-iliac synchondrosis so that the pubic bones could be brought together and wired.

Operation.—At the end of July, 1908, a lateral flap with its convexity to the right was raised from the thin cartilaginous symphysis, which was then divided vertically. The neck of the bladder and the short urethra were carefully separated from the pubic bones, which were retracted, leaving a gap of nearly an inch and a half between them. The subperitoneal fat was drawn up and the lower part of the bladder and the urethra were freely and carefully separated from their lateral attachments by blunt dissection. When the bleeding had been checked, no muscular or prostatic tissue could be seen in front of the neck of the bladder or urethra, whose anterior wall consisted of mucous membrane only. This was carefully saved. The lowest The lowest part of the anterior wall of the bladder was alsovery thin and almost devoid of muscular fibres.

By means of Lembert sutures of fine catgut the muscular and fibrous tissues upon the sides of the urethra and the lower part of the bladder were brought together in front of the carefully preserved mucous membrane, which was thus invaginated. In this manner the passage was so narrowed that it firmly gripped a No. 4 selfretaining rubber catheter, which had been inserted. The lateral separation had been free enough toprevent undue tension upon the sutures. The edges of the pubic bodies were freshened and fixed in apposition by means of wire. wound was accurately closed. At first all the urine drained away through the catheter, but this became blocked and had to be changed after the fourth day. When the instrument was finally removed there was incomplete control of the urine, both day and night, but gradually the incontinence diminished. Firm union has occurred between the pubic bones, and the gait is perfectly natural. No attempt was made to correct the epispadias, this being deferred until the result of the operation for incontinence is certain.

Six months later Dr. Richmond kindly writes: "You will be glad to know that the boy you operated on is very much better. He has much more control and can attend school without any inconvenience."

Remarks.—This case seems to be worth recording for several reasons. As far as I know this method of treating the incontinence sometimes associated with epispadias by inversion is original. All the work is external to the mucous membrane which is not injured. In former operations the edges have been pared and brought together. Professor Trendelenburg has reported several more or less successful cases of partial ectopia, which he had treated in this manner

after mobilising the sacro-iliac synchondrosis. Although the rather delicate operation was based upon anatomical and pathological information, I did not venture to expect it to be so successful as it has been. The amount of muscular tissue to be found at the neck of the bladder was uncertain, so that one wondered if it would be possible to bring it round the urethra in front without unduly narrowing the passage. The degree of control that this measure would ensure was also a matter that could not be decided beforehand, for although the nervous supply is postero-lateral, and therefore not likely to be seriously affected, I could not be certain if it would be adequate, even if the muscular approximation remained permanent. The result is, therefore, instructive, and gives rise to considerable speculation.

I was pleasantly surprised to find that the pubic bodies could be so easily retracted in a boy, æt. 6, without the need of interfering with the sacro-iliac synchondroses. A good view of the neck of the bladder was obtained when the free venous bleeding had been checked by pressure for a few minutes. I took care to preserve this mucous membrane intact, not even passing any sutures through it, so that urine might not leak into the cellular tissues a few days after the operation, when the tissues softened or the catgut sutures perchance gave way. Extensive lateral bites were secured so that the sutures might not tear through, and for greater security interrupted sutures were used. The infolding was carried well up beyond the neck of the bladder, and also into the prostatic and membranous portions of the urethra.

The muscular tissues above the neck of the bladder were brought down to the neck by means of sutures passed obliquely from each side. In this manner the circular fibres of Thomson were brought round the neck of the bladder. These lower circular fibres are supposed to be endowed with the chief sphincteric control. In enlargement of the prostate, the vesical projections pass up within a hypertrophied ring of these fibres, which are carefully preserved during the enucleation.

It is probable, however, that the muscular

prostate of the young and the compressor urethræ take their part in controlling the urine, and for this and other reasons it is wise to approximate these parts in front of the urethra. In a child this is not easy, for the cleft prostate is minute and the periurethral tissue is scanty, under the circumstances of the operation.

My best thanks are due to Dr. B. Wallis, then house surgeon, and to my dressers for their help during the operation, and for their unremitting care of the patient during his stay at Guy's Hospital.

### A STUDY OF

# TEN CASES OF OPERATION FOR PERFORATED GASTRIC ULCER. (a)

By CHARLES MORTON, F.R.C.S.,

Professor of Surgery in University College, Bristol; Senior Surgeon to the Bristol General Hospital and the Royal Hospital for Sick Children and Women.

I FIND, on looking up my records (a) that I have operated on ten cases of perforated gastric ulcer, with seven recoveries, and I propose in this paper to give a brief abstract of them, and to point out the lessons I have learnt from them. As we might expect, the

(a) "Bristol Medico-Chirurgical Journal," September, 1908.

chance of recovery depends very largely on two things one, the time which elapses between perforation and operation, and, the other, the extent of extravasation of stomach contents. The following table by Robson and Moynihan (a) shows the relation of the result to time of operation:-

	Total			
	Cuses.	Recovered.	Died.	Mortality.
Operation under 12 hours	49	35	14	28.5
., from 12-24 hours	33	12	21	63.6
" from 24—36 bours	16	2	14	87.5
" from 36—48 hours	2	0	2	100.0
over 48 hours	33	16	18	51.5

But it seems uncertain whether these statistics are taken from consecutive series of cases. If not, they will almost certainly fail to give the real mortality, for single fatal cases do not as a rule get published, Paterson found that in a series of consecutive cases operated on within twelve hours the mortality was 47 per cent., within twelve to twenty-four hours 50 per cent., and from twenty-four to forty-eight hours 83 per The difference between his first and second periods of twenty-four hours is therefore very marked. All my three fatal cases had general peritonitis. In one thirty-nine hours had elapsed between perforation and operation, in another forty-nine, and in the third three days; but one of the successful cases (Case 3) was not operated on for thirty-nine hours after perforation, but in this case the extravasation was slight, and the peritonitis localised. In two of these three cases the patient was in a very collapsed state before operation, and the third died nearly three months after operation, and some time after a subphrenic abscess had been drained. The mortality after operation for perforated gastric ulcer has been considerably reduced in the last few years, owing perhaps to earlier diagnosis. Mr. Crisp English (b) found that only 52 per cent. recovered out of forty-two consecutive cases at St. George's Hospital up to 1903; and Mr. Sargent (c) gives 58 per cent. recoveries in forty-nine cases at St. Thomas's Hospital up to 1904. Mr. Moynihan's results, published in 1906, (d) are much better—66.6 per cent. recoveries in twenty-seven cases; and Mr. Crisp English and Mr. Turner together, at St. George's Hospital, had nine cases with only one death. In my ten cases the recoveries were 70 per cent.

Diagnosis.—The diagnosis of several of my cases was not difficult, but it is worth while calling attention to what has been called the "latent period." The symptoms of onset may be most acute, and then in a few hours there may be so little pain that you are put off your first diagnosis. In Case 4 the diagnosis was much less certain when we saw the patient just before operating than it seemed earlier in the day, but fortunately we decided to operate. In other cases in this series it will be noted that the severe pain had passed away before I saw the patient. But in the latent period the rigidity will usually persist, and also a certain amount of tenderness, though the frequency of the pulse may lessen. In two of my cases appendicitis was diagnosed (Cases 5 and 7). In Case 5 the tenderness and fulness were most marked in the appendix region, and in Case 7 the history was that the pain had been there. This is not at all an uncommon mistake, especially with perforating duodenal ulcers-indeed, with the latter it is quite frequent. Extravasated fluid runs down into the right iliac region in these cases, and peritonitis is marked there. The mistake matters really very little, provided we operate, for we can easily extend our incision in the rectus up to the stomach region; but the fact that in nineteen out of fifty-one cases of perforated duodenal ulcer collected by Moynihan a diagnosis of appendicitis was made, is an additional argument in favour of early operation in all cases diagnosed as acute appendicitis with severe symptoms at the onset, at any rate in adults. It seems to me that rigidity of the abdominal wall is one of the most important signs of perforated gastric ulcer,

<sup>(</sup>a) "Diseases of the Stomach," 1901, p. 161.
(b) "Medico-Chirurgical Transactions," 1904, 1xxxvii. 27.
(c) "St. Thomas's Hospital Reports," 1904, xxxiii. 477.
(d) "Medico-Chirurgical Transactions," 1906, 1xxxix. 47L

though when general peritonitis was present in Case 8 there was neither rigidity nor tenderness, but the

patient was in a very collapsed condition.

In connection with the diagnosis of perforated gastric ulcer, it may be well to call attention to a source of error pointed out by Moynihan. (a) He says he knows of three cases in which negative exploration for perforated gastric ulcer was performed in women at the commencement of menstruation. Sharp abdominal pain, with vomiting, distension, and collapse were the symptoms and signs present. In one of his own cases (in which he did not explore) the absence of any rigidity and tenderness in the abdomen negatived perforation. There may be a history of previous similar attacks at menstrual times.

We must not fail to diagnose a case as one of perforated gastric ulcer because shortly after the onset of symptoms shock is not present. In one of my cases (Case 9) I saw the patient one hour after perforation; his pulse was 112, not very bad, nor did his general condition suggest collapse. Neither was Case , seen a few hours after perforation, suffering from collapse. Moynihan says (b) that within the first two hours, though the pain is very severe, there is no rigidity or collapse, or any marked rise in pulse rate. However, in one case I saw an hour after perforation the whole abdomen was very rigid, and I believe collapse may be very marked. Mr. Pearce Gould ( $\epsilon$ ) refers to a case of sudden death from the shock of per-

forated gastric ulcer.

Treatment.—The method adopted for cleansing the peritoneal cavity differed in the successful cases-in some I sponged, and in others I flushed. If the extravasation and effusion of fluid and lymph is localised, it seems to me that it is unwise to risk further dissemination by flushing. In cases in which extravasa-tion or inflammatory effusion is widespread, especially if stomach contents are widely diffused, perhaps flushing is the more satisfactory method, as there is less manipulation, and therefore less tendency to shock, and I should expect the cleansing to be rather more thorough than with sponging, if plenty of saline solution is used; (d) but I have learnt from my experi-ence of the treatment of diffuse peritonitis from appendix disease how well most cases do after sponging, and unless there were evidence of very wide—almost general-diffusion of infective material, there is a risk of infecting fresh areas in flushing. Paterson is opposed to irrigation, because he has observed when giving the anæsthetic that if the patient was not very deeply under, when flushing was used there was weakening and quickening of the pulse. But he does not tell us if he has observed the effect of sponging on the pulse. He only recommends sponging of the space "above and behind the liver." He suggests sucking out the fluid from the pelvis. He avoids sponging, because he thinks it will interfere with peristalsis after operation, and he seems to depend more on the action of purgatives after operation to cleanse the peritoneal cavity than on flushing or sponging at the time of operation. I should rather still be inclined myself to act on advice given by Pearce Gould more than ten years ago-not only to operate early, but to spare no pains in thoroughly cleansing the peritoneal cavity.

If the intestines have to be turned out of the abdomen in order to get room to flush, then I think there would be greater shock with flushing than with sponging; but then sponging without evisceration would probably not be effectual in cleansing the peri-

toreum because of the tight packing of the intestines.

In all the eight successful cases of Crisp English and Turner (e) irrigation was employed, and suprapubic and loin counter-openings made before the irrigation was started, so that free exit for the fluid was provided. In nearly all the cases the supra-pubic openings disclosed a pelvic collection of "peritoneal fluid and stomach contents." This shows how im-

portant it is in all cases of perforated gastric ulcer to examine the pelvis, if not by a separate opening, at any rate by inserting into it a sponge on a holder. If fluid is found, then I should certainly make a supra-pubic opening for cleansing and drainage, but I should not do so in every case, nor make counter-openings in the loins either. The right kidney pouch and the left loin can both be drained by long split tubes with gauze wicks from the anterior ab-dominal wound, but in some cases of very extensive infection of one or other loin no doubt a counter opening there would be advisable. In every case, even though the extravasation or the peritonitis was quite localised around the perforation, I should certainly drain, and of all drains the split drainage tube with gauze wick seems to me the best. Barker (a) has recorded twelve consecutive cases of perforated gastric ulcer treated by sponging, with five recoveries. If we compare the results with Crisp English and Turner's after irrigation, we must remember that so much depends not only on the period which elapsed between the perforation and the operation, but on the extent of extravasation of stomach contents, that we can hardly conclude that irrigation is the best method to

employ in all cases.

In all my cases but one I have been able to close the perforation by suturing, though in some it was very difficult to get the stitches to hold in the indurated friable tissue around the perforation, and in several the suturing was supplemented by an omental graft. In Case 4 I could not suture, the induration around the perforation was so great, but omental grafting alone answered well. It is a mistake to suppose that free gas is always present in perforated gastric ulcer. It was suggested some years ago that all that was necessary to settle the diagnosis of doubtful cases of perforated gastric ulcer was to make a very small incision and see if free gas was present. If this test had been relied on, many perforations would have been missed. You must examine every part of the stomach. If you find no perforation anteriorly, you must divide the gastro-colic omentum, and examine the posterior surface of the stomach, though perforations here are rare. All my ten cases were anterior perforations. You are often led to the perforation by increased redness and lymph deposit perforation by increased redness and lymph deposit on the wall of the stomach, and by pressure on it gas and stomach contents may be forced out. It has been suggested that air may be pumped through the perfcration through an œsophageal tube passed from the mouth, but pressure on the stomach ought to be sufficient to cause the exit of gas or fluid at the perforation. Because free gas is often not present in the peritoneal cavity in these cases, there may be no alteration in the liver dulness. I should say there alteration in the liver dulness. I should say there rarely is obliteration of it, even if free gas is present. In a distended abdomen it may be obliterated from distension of the intestines, but in a flat abdomen I have seen it absent and no free gas present, so that I do not regard the presence or absence of liver dulness as a very reliable guide in these cases. Barker (b) has come to much the same conclusion from a study of his twelve cases. He found liver dulness present with abundant free gas, and absent without any free

I have never felt inclined to adopt the suggestion made of late years by some surgeons, to do gastro-jejunostomy as well as close the perforation. Patients with perforated gastric ulcer do not seem to me suitable cases for any more operative interference than is absolutely necessary to save life, even in cases of early operation, and they do very well with suture alone if peritonitis has not already set in. Nor, for the same reason, should I excise a perforated gastric ulcer, though several surgeons have done this, but not with much success. (c)

Mayo Robson says (d) that if the patient's condition will permit of it, the question as to the performance of gastro-jejunostomy should be considered, because other ulcers may be present and will be cured, and if on the point of perforating, perforation will be pre-

vented, the sutured ulcer will heal better, there will be less risk of hæmatemesis, saline purgatives can be given, and will assist in the absorption of peritoneal fluids, and early mouth feeding can be resorted to. Paterson (a) recommends it for much the same reasons, and Moynihan (b) seems inclined to recommend it in early operations, to aid the healing of the sutured ulcer, and to cure others which he says are usually present. As he points out, if in closing the perforation we have to seriously narrow the pyloric part of the stomach, it may be absolutely necessary, but the other reasons seem to me hardly urgent enough to demand it, for even though 'he operation is done early and the patient may bear the earlier stage of the operation well, yet we must remember that there has been very severe pain, and the less manipulation of the abdominal viscera the better.

It may be necessary to do gastro-jejunostomy later for the condition of the stomach resulting from the ulcer, or if the ulcer will not heal with prolonged medical treatment. In one of my cases (Case 4) I had to do the operation for "hour-glass" stomach, due to contraction of a chronic ulcer six months after the closure of the perforation. But because gastro-jejunostomy may ultimately be necessary, I should not do it at the time of closure of the perforation. Some surgeons would, however, regard the possibility of later trouble as an argument for the performance of gastro-jejunostomy at the time of closure of the perforation.

CASE 1.—Mrs. M., 40, March, 1908. Children's and Women's Hospital. History of pain and vomiting after food for some months. Pain very severe below left costal margin, extending up chest into left arm. Came on three hours after dinner. Four hours later seen with Dr. Osmond Bodman. Not then in much pain, but could not breathe deeply. Pulse under 100. Abdomen tender and rigid almost all over, but especially just below left costal margin. Three and a-half hours later tenderness and rigidity were much less, but still marked below the left costal margin. She seemed easy, and could breathe more deeply. Operation eight hours after perforation. Perforation in section eight hours after perforation. Perforation in arterior wall, near esophageal orifice, with free escape of gastric fluid, but no free gas. Brown fluid in pelvis and lymph in both renal regions, as well as in region of stomach. Perforation sutured. Infected parts thoroughly sponged. Supra-pubic drainage open-ing, and drainage tube into right loin and splenic region from original wound. No shock. She made a good recovery. Feeding by nutrients only for 14 days, and then by liquid only for some time.

CASE 2.—Miss B., 25, January, 1907. General Hos-

pital. At onset very severe epigastric pain, four hours after a light meal, and continued for hours until opium given. I saw her with Dr. Cook thirty-five hours after perforation. There was then very little pain, and there had been no vomiting save a little retching at five years ago, and a little epigastric pain a few days before. Considerable general tympanitic distension was present, with tenderness and rigidity under the left costal margin. Pulse, 140; temperature, 102°. Operation 37½ hours after perforation. Perforation on anterior surface, just below lesser curve, and 3 in. from pylorus. Sutured, and omental graft used. Lymph and serous fluid in upper abdomen, including right kidney pouch, none in lower. Sponged. No counter openings, but many drainage tubes with wicks. Moderate shock. Fed by nutrients only for some time, then liquids only. Twenty-four days after operation began to expectorate pus, and serous fluid found at left base. Both conditions cleared up. Discharged quite well two months after operation.

CASE 3.—Rose G., 20, November, 1906. General Hospital. Epigastric pain after food 14 days. Onset 6.30 a.m. before any food taken, and very severe pain in epigastrium. I saw her thirty-six hours after perfora-tion (had taken milk in meantime), and then she was not in pain. Moderate general distension, with slight general tenderness, but marked tenderness and rigidity over upper left rectus. Condition essentially the same three hours later. Pulse 120. Operation thirty-nine hours

after perforation. Upper left rectus remained rigid even under anæsthetic. Localised peritonitis about stomach. Perforation in lesser curve near œsophagus. Sutured. Pulse 140, but not feeble at end. Fed by nutrients only for 14 days. Discharged well about six weeks after operation.

Case 4.—Miss R., 45, April, 1905. Gastric pain and vomiting for one month, and same symptoms with hæmatemesis some years before. At onset very severe abdominal pain, so that she could not move, and felt 'as if something had broken in her side." Dr. Michell Clarke saw her seven and a half hours after perforation, and I saw her with him shortly after. Pain was then severe in epigastrium and left loin anteriorly, and she could not breathe deeply enough to speak plainly (as in Case 1). Pulse 120, not feeble. No vomiting. Twelve hours after perforation she was quite free from pain (no morphine) and pulse was less rapid, but the upper abdomen, especially the upper part of the left rectus, was very rigid and very tender. Operation thirteen and a half hours after perforation. Perforation in lesser curve. There was very great induration around, so that it was not possible to suture. The perforation was closed by an omental graft. There was only localised extravasation of stomach contents. Sponging and free drainage. No serious shock.

Sponging and free drainage. No serious shock.

CASE 5.—K. M. (female), 19. March, 1905. General Hospital. Suffered from epigastric pain and nausea for some time. At onset very severe pain, "doubling her up," and vomiting. Pain and vomiting continued. Seen by me about forty-six hours after perforation. Pulse 140, feeble; temperature 100.6°. Tense general abdominal distension and tenderness, most in right lower abdomen, but no rigidity. The greatest tenderlower abdomen, but no rigidity. The greatest tenderness and fulness being in the right lower abdomen, I opened the abdomen here forty-nine hours after peropened the abdomen here forty-nine nours after perforation, thinking it might be appendix trouble. I found a diffuse purulent peritonitis. Perforation was near the pylorus, and covered by lymph. Lymph peeled off, and perforation sutured. Sponged and counter opening for drainage made above pubes. Multiple drains. By fourth day much better. Pulse Number of the property of the nearly three months after operation. At post-mortem, perforation sutured at operation found as a scar, and another ulcer had perforated, but was closed by adhesions. An abscess was found in the liver, and a considerable quantity of serous fluid with flakes of lymph in the pelvis, and a little pus was shut up amongst adherent coils of intestine.

CASE 6.—Mabel R., 14, November, 1904. Children's and Women's Hospital. Epigastric pain and vomiting for a week. Then severe sharp pains, which persisted, but she walked from City up to hospital the next morning, after a light breakfast, when the pain got more intense, and she became collapsed. It is not easy in this case from the symptoms to fix the time of perforation, but from the condition within the abdomen I should say it took place that morning, and that the other symptoms were due to peritonitis at the base of the ulcer. I saw her about two hours after the most intense pain came on. The abdomen was board-like all over, and tender below the left costal margin, and in left iliac fossa, and hardly at all dis-tended. The severe pain had gone, and she only had pain on breathing deeply or moving. Operation four hours later. Then temperature 102°. Perforation on anterior surface near pylorus was found and sutured. clear fluid in left iliac fossa and pelvis. Irrigated with counter-opening for drainage above pubes. Lymph on stomach, but no general peritonitis. No shock. Discharged well a month after operation.

No complications.

CASE 7.—E. C. (female), 25, May, 1908. At onset severe abdominal pain. Seen with Dr. Eberle and Dr. Walker Dunbar thirty-six hours after perforation. Another severe attack of pain ten and a half hours before I saw her. Pain had been on right side of

abdomen, and ruptured appendix abscess was diagnosed. Temperature had been 1020 earlier in the day. Pulse too feeble to count, and she seemed too bad to have much chance of recovery, but her relations wished to give her any slight chance which operation might give, if she died under it. Abdomen was much distended, rigid, and generally tender. Operation thirty-nine hours after perforation. Perforation near pylorus on anterior surface, with general peritonitis.

Flushed. Died at end of operation.

Case 8.—Male, 18, May, 1903. General Hospital.

Onset with severe pain in left abdomen. Supposed to be suffering from pleurisy before admission. Friction heard, probably peritoneal. Admitted three days after perforation, and when seen by me a few hours after admission pulse was very feeble (130) and extremities chilly, though a warm evening. Abdomen distended with shifting dulness, but no tenderness or Immediate operation. Perfor Perforation on anterior surface near pylorus. General peritonitis. Flushed. Died soon after.

CASE 9.—Mr. V., 45, July, 1903. General Hospital. Had been medical out-patient for gastric symptoms before onset of severe general abdominal pain and vomiting, when lifting a heavy weight. Seen an hour after. Then in great pain all over abdomen, and abdomen very rigid and tender all over. Loud friction heard over lower part of left chest below nipple. Operation five hours after perforation. Perforation on anterior surface close to pylorus. Sutured. Fluid widely extravasated. Flushed. No shock. Fed by nutrients only for ten days, and then only liquids for a time. Discharged well about two months after a time. Discharged well about two months at operation. Some bronchitis the only complication.

CASE 10,-E. M. W. (female), 26, October, 1901. General Hospital. For three months subject to epigastric pain. At onset severe pain below left costal margin, ten and a half hours before I saw her, when laughing, and two hours after taking a teacup of arrowroot. Had had two previous severe attacks of pain, two days and four days earlier. When I saw her she was not in any pain, but had taken a pill to relieve the pain (prescribed by her doctor) four nours earlier. Abdomen was rigid all over, and very tender below left costal margin. Operation eleven hours after perforation. Perforation near œsophageal orifice on anterior surface, and very difficult to reach. Only localised extravasation. Sponging.

### REMARKS UPON

### SOME GONORRHŒAL DISEASES OF THE EYE. (a)

BY SYDNEY STEPHENSON, M.B., C.M., F.R.C.S.E.,

Ophthalmic Surgeon to the Evelina Hospital, the Queen's Hospital for Children, and Queen Charlotte's Hospital.

THAT the professional conception of gonorrhœa is different from what it was not so very many years ago, is a self-evident proposition that will be disputed by no well-informed medical man. We now recognise that gonorrhœa is not always a harmless local order, perhaps the worst result of which might be a strictured urethra, as was generally thought twenty-five or thirty years ago.

There have been two main changes in medical

opinion:—(1) That systemic infection by the gonococcus is commoner than was once supposed. These infections appear to take place only in cases where the posterior urethra and contiguous structures are involved. Modern researches go to show that the gonococcus itself is responsible for the infection, and it may now be fairly claimed that the  $r\delta lc$  of so-called "mixed infections" and of gonotoxin is becoming less and less important as a cause of the metastases. These infections include arthritis ("gonorrhœal tism"), endocarditis, pleuritis, peritonitis, iridocyclitis, teno-synovitis, and, lastly, septicæmia and pyæmia. Every single one of the conditions named

(a) Based upon a Clinical Demonstration given at the Polyclinic, London, on May 8th, 1908.

implies infection of the blood with gonococci, and, in point of fact, the organisms have been often found in that fluid. It is difficult to say why one individual should escape general infection and another develop Traumatism, in some cases, at all events, takes a share in the process. Moreover, it is possible that certain strains of gonococci are more virulent than In this connection Ahmann's experiment is suggestive. Ahmann (1) inoculated the urethra of a healthy subject with gonococci from the blood of a man suffering from systemic gonorrhoral infection. The result was that the first subject developed not only urethritis, but septicæmia as well. (2) That the disease may persist as regards infectivity for an almost indefinite period. This is the theory of "latent gonorrhœa" placed prominently before the profesgoinfine placed prominently before the places sion more than thirty years ago by Emil Noeggerath. Noeggerath (2) maintained that 90 per cent. of the cases of gonorrhœa remained uncured, and that, of the women who married men once affected with gonorrhœa, few remained healthy, the rest suffering from various induced ailments, such as endometritis or metritis, pyosalpinx, salpingitis, evaritis, or perimetritis. The disease might lurk indefinitely in the follicles of the male urethra, and cause infection when transplanted upon a suitable soil, such as the mucous membrane of the vagina or eye. Noeggerath's views were received with incredulity at the time he stated them, but I am under the impression that they are nowadays generally accepted, although, perhaps, in a somewhat modified form. That latent gonorrhoea has an important bearing upon the ætiology of some affections of the eye will be explained immediately.

It is now well understood that several diseases of the eye are connected with gonorrhoma as cause and effect. Until comparatively recent times the list of such affections was a restricted one, and included, in fact, but ophthalmia neonatorum and adultorum, and iritis. It now comprises such affections as metastatic conjunctivitis, inflammation of the lachrymal gland and of Tenon's capsule, scleritis, and (in rare instances) neuritis, neuro-retinitis, and retinitis. On the present occasion, however, I shall confine my remarks to what may be called inoculation-affections of the eye, or, more briefly still, cases of gonorrhœal ophthalmia. For an account of the other gonorrhœal diseases of the eye I would refer readers to an excellent monograph (3) recently published by Dr. W G. M. Byers, of Montreal.

Gonorrheal inoculations of the conjunctiva may take place at any period of life—literally from the cradle to the grave. They depend upon the conveyance of specific discharges to the eye, either directly, as by a spurt of "matter," or indirectly, as by fingers, towels, sponges, water, and so forth. They include towels, sponges, water, and so forth. three clinical types :-

1.—GONORRHEEAL OPHTHALMIA.

2.—LEUCORRHŒAL OPHTHALMIA.

-OPHTHALMIA NEONATORUM.

It must be borne carefully in mind that, although the forms of ophthalmia named above differ a good deal as regards clinical appearances and prognosis, yet each is due to the gonococcus. This fact will prepare the reader to accept the statement that a scientific and assured diagnosis can be reached only by bacteriological examination of pus from the inflamed eyes.

The methods of investigation are simple, and call for nothing more than an acquaintance with routine laboratory methods. As a preliminary step, the affected eye is washed free from discharge with warm saline lotion or with any sterile indifferent fluid. After waiting for a few moments, a trace of secretion which has in the meanwhile accumulated should be lifted from the conjunctival sac by means of a sterilised platinum loop, care being taken not to touch the lids, lashes, or neighbouring parts with the instrument. The discharge is then spread as thinly as possible over the surface of several bacteriological (No. 1) coverglasses, which are allowed to dry, protected from dust by a watch-glass. The next step is to stain the specimens. One should be treated with a basic aniline colour, of which the best is carbol methylene blue, and the other by Gram's method, safranin or weak fuchsin being employed as the counter-stain. Gono-

cocci will be seen as biscuit-shaped diplococci, which show a special tendency to become grouped in the pus and on the epithelial cells contained by the specimen. They are completely and rapidly decolourised by Gram's method. As a rule, the micro-organisms are present in large numbers, a point which is by no means devoid of practical importance.

It must be borne in mind that Gram-negative micrococci other than gonococci are occasionally found in the conjunctival sac, normal or diseased. The most the conjunctival sac, normal or diseased. important of these are two in number-namely (1) the meningococcus, and (2) the micrococcus catarrhalis. In rare cases these organisms may prove a source of But the first-named are larger and differ in shape, while the second present also more or less appreciable differences as regards size, arrangement, and grouping, as compared with gonococci. As a rule (to which exceptions are practically non-existent) it may be said that a severe discharging inflammation of the conjunctiva in baby, child, or adult, associated with numerous intra-cellular cocci and diplococci, which rapidly lose their gentian violet when treated with absolute alcohol in Gram's method, can be no other organism than the gonococcus. The difficulty is with mild cases. Under such circumstances, before organisms can be exactly differentiated, it may be necessary to resort to culture tests, and, indeed, in a specially difficult or important case, agglutination tests may have to be employed before one can distinguish between gonococci, on the one hand, and meningo-cocci, on the other. At the same time it is necessary to note that the meningococcus has seldom been found in the conjunctival sac, and never, so far as I know, in association with ophthalmia neonatorum. On the contrary, by Axenfeld (4) and Brons the micrococcus catarrhalis has been shown to occur more frequently on the conjunctiva than was once believed. Although in Brons's cases there existed a mild type of chronic conjunctivitis, yet it is still a moot point whether the micrococcus catarrhalis is or is not pathogenic as regards the human conjunctiva.

To recapitulate, the diagnostic features of the gonococcus are:—(1) Its predilection for the interior of the polymorphonuclear and other cells contained in the specimen; (2) its ready and rapid response to Gram's stain; and (3) its restricted growth upon all media, except such as contain hæmoglobin.

1.—GONORRHŒAL OPHTHALMIA.

Gonorrhœal ophthalmia as it affects adults is a most formidable affection of the eye, but owing to the care exercised nowadays, it is happily a rare disorder. There must be ophthalmic surgeons of the younger generation who have never seen a case. Speaking for myself, I have myself met with but few, and those mostly in nurses who had inoculated themselves from cases of gono-ophthalmia in babies. ease is usually confined to one eye, and in fully onehalf of the cases entails more or less damage to the cornea.

The following instance of the disease fell under my notice a year or two ago :-

A housemaid, æt. 25, was seen on September 8th, 1906, her right eye showing the clinical appearances that one associates with an attack of acute muco-purulent conjunctivitis—that is to say, the symptoms were not severe. The lids of the left eye, however, were red and so swollen that they could scarcely be opened. There was considerable purulent discharge. Chemosis was pronounced, but distributed irregularly. The cornea, although hazy, was not actually ulcerated. The unfortunate girl volunteered the statement that her sweetheart, a soldier, had given her gonorrhoea, and had put her into "the family way," and, to complete the sordid story, had deserted her.

Specimens of pus taken from the left eye contained

relatively few groups of intracellular cocci, but those present were characteristic enough. When treated by Gram and counter-stained by weak vesuvine, the organisms took the brown colour of the latter. Secretion expressed from the girl's urethra also showed the presence of gonococci.

The case was treated with quinine sulphate lotion (4 grs. to the unce), used frequently, and by the application once a day to the everted conjunctiva of a solution of argyrol, 25 per cent.

September 12th, 1906.—Both eyes about equally affected, and gonococci present in the discharge from patient now presented the typical appearances of gonorrheal ophthalmia affecting both eyes. The symptoms, however, were more marked in the left eye, the cornea of which was on the point of perforating. The right cornea showed a few minute grey infiltrations near its edge. September 19th, 1906.—Marked chemosis. Right cornea cloudy. The left cornea has perforated, and a protrusion of Descemet's membrane is now present. Patient complains of much pain, and is worn out by anxiety as to the fate of her eyes. September 22nd, 1906.—Patient, who complains of less pain, is now able to open her eyes a little. The right cornea shows a purulent infiltration involving the inner half, while the rest of the cornea is cloudy. further note is forthcoming.
2.—LEUCORRHOGAL OPHTHALMIA.

In a small but important class of case purulent ophthalmia is met with in children who suffer from ophthalmia," the existence of which was known to some of the earlier writers, was identical bacteriologically with ophthalmia in babies and with gonorrhoeal ophthalmia in adults. In this country Mr. Edward Nettleship (5) has drawn attention to the existence of such cases, although without admitting their gonorrhoal identity.

The following is a good example of this form of ophthalmia:---

Maud H—, æt. 21, was brought to the Evelina Hospital, London, on March 2nd, 1908, for a severe discharging inflammation of the right eye of one week's duration. There was a small infiltration towards the centre of the cornea. The clinical appearances recalled those of a gonorrheal case, an observation that led me to examine the child generally, when I found a profuse discharge from the vulva, of which the mother had said nothing. Gonococci were discovered in the discharge both from the conjunctiva and the vulva.

The child was admitted to hospital. The inflamed eve was treated with argyrol, 25 per cent., six times a day, and was meanwhile kept clean with oxycyanide of mercury lotion, 1-4,000. Atropine was also used. The non-affected eye was protected against infection by Buller's well-known sticking-plaster and watch-glass shield. The vulvo-vaginitis was treated with

hot permanganate lotion, 1—5,000.

The child was discharged from hospital on May 2nd, after a stay of two months. The left eye did not become involved, and the other eye healed with the production of a small nebula of the cornea.

Some years ago I met with a case of gonococcal ophthalmia in the right eye of a small boy, æt. 7, who was also affected with urethral gonorrhœa. origin of the latter was never traced.

Gonorrhœal ophthalmia in a child need not, however, be the product of an auto-infection. In the case to be next narrated, infection appears to have origin-

ated from a latent gonorrhoa in the father

Cerise B——, æt. 2/12, was first seen on November 10th, 1906, at the Kensington General Hospital. The mother presented no obvious evidences of gonorrhœa. The father had suffered from gonorrhæa about twelve months ago, and had continued to occupy the same bed as the child until the latter's eye became inflamed four days ago.

Present state.—The clinical appearances of the left

eye recall those of gonococcal ophthalmia-that is to say, there is purulent discharge, the upper lid is red, heavy, and swollen, and the cornea is universally cleudy. There is a thin layer of inseparable menibrane on both lids, better marked upon the upper than the lower one. The child is ill in herself, with a temperature of 101° F. Throat not affected. No vulvo-vaginitis. Bacteriology.—Smears from the pus, stained with Loeffler's blue and with Pappenheim, showed tolerably numerous cocci and diplococci, together with cell-groups of those micro-organisms Treated with Gram and vesuvine (0.5 per cent.), they were stained by the last-named reagent.

The child was admitted as an in-patient at the

Queen's Hospital for Children, and her subsequent history may be stated in a few words. On November 14th the right eye was definitely affected by the disease. On the following day both eyes were typical of gonorrhoal ophthalmia. The left cornea was hazy, and bulged towards the centre. On the 20th smears from the eyes showed an abundance of gonococci. Cultures were negative. On December 19th a note was made to the effect that an adherent leucoma was present in the lower-inner quadrant of the left cornea, the rest of which retained its transparence. On January 10th, 1907, an iridectomy was made in the upper-outer part of the left iris, and on February 6th and March 14th, 1907, the leucoma was tattooed.

### **OPERATING THEATRES.**

PADDINGTON GREEN HOSPITAL.

EMPYEMA.—MR. ARTHUR EDMUNDS operated on a girl, æt. 3, who had been the subject of pneumonia for three weeks. Unfortunately the resolution had been incomplete, and the temperature had begun to go up once again, and an area of distinct dulness appeared on the left side. The chest was tapped about the level of the angle of the scapula, and pus was obtained. In suspected cases of empyema, Mr. Edmands said, exploratory tapping is of the very greatest value. In the first place, it is, of course, evidence of the pre-sence and locality of the collection of pus; in the second place, it enables the organism which is causing the empyema to be identified; and, finally, by removing a certain amount of the fluid, it diminishes the intra-pleural tension, and, by allowing the heart to accommodate itself to the altered conditions, minimises the operative risks. Several points need to be attended to in this connection. In the first place, the exploration of the chest must be conducted with the most aseptic precautions. The fallacy that the presence of pus allows the relaxation of antiseptic precautions nowhere yields such pernicious results as in the treatment of empyema. In spite of the teaching of modern day pathology, and in spite of clinical experience, it is no uncommon thing to hear the statement made that there is no occasion for antiseptic precautions, masmuch as the case is septic already. The pus which is withdrawn should always be carefully examined. Although the operation will often of necessity follow too closely upon the exploratory puncture for elaborate cultural investigation, it is always possible to examine a film. The practical point to be settled is whether the empyema is due to a pure pneumococcal infection or to an invasion by other organisms, either as a pure or mixed infection. This is an extremely valuable point for treatment. The pneumococcal empyema resolves readily, and if the lung has not been compressed too severely, yields very rapidly. In mixed infections and in empyemata due to other organisms, such as the staphylococcus pyogenes, the bacillus coli communis or the tubercle bacillus, healing is more protracted, and usually takes place by slow obliteration of the cavity. It was decided to drain the cavity by resecting a portion of rib just above the site of the exploratory puncture. The child was accordingly anæsthetised with chloroform. There is little doubt, Mr. Edmunds pointed out, that the anæsthetic in these cases has risks of its own, but if a certain amount (that is to say, 1 to 2 oz.) of pus is evacuated at the time of the exploration, and a minimum quantity of anæsthetic given, the risks are not unduly great. After the skin had been disinfected, the index and middle finger were placed over the intercostal spaces on either side of the rib to be removed, so as to steady the superficial structures. When this is done, it is possible to carry the knife at once down to the bone and to divide everything from skin to periosteum cleanly. If the tissues are not steadied in this way, the contraction of the superficial muscles is apt to divert the knife from its course and make an irregular wound. When about an inch and a-half of rib had been thus exposed, a curved raspatory was passed between the rib and the periosteum, care being taken to keep close to the bone in the sub-costal groove so as to avoid injury to vessels and nerves. The bone was then cut across at each end of the incision, and the central portion removed. The soft tissues on the deep surface of the rib were punctured, and the opening rapidly enlarged to allow the introduction of the index finger, which was thrust into the chest so as to explore the cavity, and at the same time prevent the too rapid evacuation of pus. At this stage of the operation the anæsthetic was-stopped, and the patient permitted to come round to a certain extent, so as to allow the reflex laryngeal contractions by means of which the lung on the affected side is inflated, to come into play. As in the present case, the organism had been found to be a pure pneumococcus, the presence of masses of fibrinous material was suspected, and these soon came into view, being forced up into the opening in the chest wall and removed. A drainage tube sufficiently long to reach through the chest wall was stitched into position, a dressing applied, and the patient taken back to bed.

Mr. Edmunds remarked that in suturing tubes into empyemata care must be taken to fasten them so that about half an inch protrudes from the chest wall, otherwise they are very liable to slip under the edges of the wound and become occluded. The drainage tube in a pneumococcal case in a child is removed on the fourth day, and in the majority of cases no further drainage is found necessary. In dressing these cases what he had before said on the question of antiseptic precautions must be rigidly observed; indeed, there is no operation in the whole of surgery which requires such minute care as the dressing of empyema: the persistent discharge may be due to a hopelessly adherent lung, but in the majority of cases it is due to repeated re-infection at the time of dressing. Much has been written as to the mechanism by means of which the lung is re-inflated and with regard to the existence of adhesion (in the physical sense) between lung and chest wall, and has been brought forward to explain this phenomenon. With a wide perforation in the thorax the ordinary suction pump action of the chest is thrown out of action, as far as the lung on that side is concerned, but upon the sound side, owing to the comparative rigidity of the mediastinum, the normal respiratory mechanism is quite efficient and coincidentally with the enlargement of that side of the thorax air enters the normal lung. At the commencement of expiration the glottis is closed and the air, unable to escape through the trachea, is forced into the affected lung, distending it and bringing it into contact with the chest wall, the glottis finally opening, air escapes and expiration is complete. Respiration, therefore, consists in these cases of three phases-inspiration, distribution, expiration.

### TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

OBSTETRICAL AND GYNECOLOGICAL SECTION.

MEETING HELD THURSDAY, JANUARY 14TH, 1909.

The President, Dr. HERBERT SPENCER, in the Chair.

Dr. Florence E. Willey read a short communication on the

HISTOLOGY OF THE SMALLER MYOMATA.

Reference was made to the fact that the more recent theories have claimed that fibro-myomata originated by proliferation of the cells forming the coats of

arteries or capillaries, and that the muscle fibres are arranged concentrically round a central vessel.

Sections of young myomata, from 5 m.m. diameter upwards, illustrate the following points:—

(1) That the proliferating cells in growing tumours are muscle cells.

In sections from patients, æt. 30—40, with enlarging uteri, the areas of proliferation show less connective tissue in proportion to the muscle than is found in non-proliferating muscle bundles of the same uterine wall, and the muscle nuclei are oval to rod-shaped; whereas seedling tumours past the menopause consist largely of fibrous tissue, and the muscle cells have narrow rod-shaped nuclei.

(2) The cells which proliferate are not those of the vascular system, but cells common to the whole uterine

parenchyma.

(3) The shape of early growths is most variousdepending on the direction of the muscle bundles concerned rather than on any relation to vessels large or small. Capsule formation begins later, when the growing tumour assumes an oval or spherical shape.

(4) Subperitoneal fibro-myomata often begin by proliferation of the muscle bundles immediately beneath the peritoneum, and capsule formation in these is

first seen on the site adjoining the uterine wall.

(5) In sections of 60—70 uteri of all ages no fibromyomatous seedling has been found before puberty, and those in women past the menopause consisted

largely of fibrous tissue.

Conclusion: That fibro-myomata arise as irregular patches of proliferation of muscle cells of the uterine parenchyma, which have no special relation to the vascular system. The cause of this proliferation is unknown, but the absence of growing tumours before puberty and after the menopause suggests some relation to the activity of the sexual organs.

The PRESIDENT (Dr. Herbert Spencer) said he could corroborate Mrs. Willey's statements as to the absence of capsules in many small fibroids, and had been surprised to hear it asserted that they always had capsules. He asked whether Mrs. Willey had examined microscopically some of the curious minute fibroids sometimes seen beneath the peritoneum, which had the appearance of keloid scars.

Dr. HEYWOOD SMITH considered that they were often the result of the suppression of sexual impressions, and that intermittent and perhaps periodic congestions, leading in some instances to small interstitial hæmorrhages, might be the starting point of the fibrous deposit, which was a morbid attempt to strengthen the

part subjected to the hæmorrhagic strain.

Dr. MACNAUGHTON-JONES noticed Mrs. Willey had excluded sepsis as an occasional factor in the extiology of some myomata. Dr. Mary Dixon Jones, who had very exhaustively studied the origin of myoma, considered that there was an infective starting point in their origin, and other observers confirmed this. From the very small size of the growths examined by Mrs. Willey, he thought it difficult to draw general conclusions as to the origin of the larger myomata.

Mrs. WILLEY replied.

In a short communication Mrs. STANLEY BOYD, M.D., gave the remote results and post-mortem findings four and a-half years after operation, in a case of

### ABDOMINAL HYSTERECTOMY

for cancer of the cervix, followed by vesico-vaginal The case was an early one, and, except for adhesions about the appendages, and some tough, fibrous tissue in the neighbourhood of the bladder, favourable for a radical operation. Vesico-vaginal fistula developed six days after the operation, but was small, and gave the patient comparatively slight inconvenience, so that she persistently declined opera-tion for its closure. The case was watched for four and a-half years, during which time there were intermittent attacks of pyuria, which were attributed to suppuration in the neighbourhood of the bladder bursting into it.

In August last the patient was admitted into the Great Northern Hospital with suppuration about the right kidney, under Mr. Peyton Beale, too ill for anything but incision of abscesses and palliative treatment. She died September 12th, 1908.

The post-mortem showed no recurrence of growth,

but complete occlusion of the right ureter at its vesical end, where it was imbedded in a mass of cicatricial tissue, right pyonephrosis, perinephric suppuration, sub-diaphragmmatic abscess, and right empyema.

The PRESIDENT (Dr. Herbert Spencer) said the pub-

lication of after-histories was of great value, especially in cases of carcinoma. It was unfortunate that a microscopic examination was not made of the fibrous tissue around the ureter and of the glands. He had often wondered what happened to patients with ureteral fistulæ when the fistulæ closed, as Wertheim had shown that they frequently did, and whether the extensive removal of the tissues around the ureters might not lead to cicatricial obstruction of these tubes.

Dr. A. H. Lewers said that he had had a case of vaginal hysterectomy for carcinoma of the body of the uterus many years ago, in which a ureteral fistula had developed. Nothing of an active kind was done for it, and some months later the fistula healed. The patient was seen several times subsequently, and there

was no evidence of anything wrong with the kidney.
Dr. G. F. BLACKER stated that he had had three cases of ureteral fistula occurring after total abdominal hysterectomy. In the first case, owing to septic changes, the corresponding kidney had to be removed, and this was followed by complete recovery. The second case developed an attack of acute suppression of urine, lasting 24 hours, about five weeks after the operation. This passed off, and the patient recovered, and the fistula healed. In the third case the patient developed a high temperature a month after the operation, and the bacillus coli was found in the urine. Eight weeks after the original operation the patient died with symptoms of pyæmia, and at the post-mortem examination a small abscess was found at the site of the fistula.

Mr. STANLEY BOYD replied.

Dr. R. H. PARAMORE read a paper on the

RÔLE OF THE PERINEAL BODY IN LABOUR

In it he stated that the perineal body plays no part in the support of the viscera, nor does its rupture facilitate prolapse. Yet the perineal body exercises a far-reaching influence during child-birth which is neither necessary nor good. In the descent of the fœtal head through the outlet of the pelvis, the pelvic floor becomes transformed into a broad, gutter-like declivity, at the lower end of which the posterior commissure of the pubo-rectalis muscle is found. The dilatation of the anus and the increase in length of the base of the perineal body shows how much the tissues below the pelvic floor stretch. The tension of these thinnedcut perineal tissues determines the more forward projection of the anterior segment of the head, the head being ovoid in shape. If the vulvar aperture is destroyed by a laceration, the movement forward of the anterior segment of the head does not occur. is evident that a perineal tear by allowing birth with the least possible distension of the muscle may undoubtedly in many cases prevent an injury which pre-disposes to prolapse. An early perineal tear may be a blessing in disguise. Perineal tears, when they do not involve the sphincter, are trifling injuries, and the only reasons for suturing them are to check hæmorthage and prevent infection. The main mass of the pelvic floor musculature passes behind the anal canal and remains intact, in spite of such a tear. The continued extension of the head can be prevented by adopting the method of Toff. When the head appears at the vulva, two fingers are placed between it and the pubes, and traction exerted backwards. taneously the head may be pressed downwards and forwards from above the anus.

Dr. Macnaughton-Jones said he would be sorry to think that it should go out from this Section that there should be any divergence from the obstetrical rule of at once closing a perineal tear. Rectocele and vesicocele constantly occurred with what Howard Kelly called "relaxed vaginal outlet," where there was no apparent laceration, but in which the perineum was weakened.

Dr. AMAND ROUTH thought that there could be no possibility of doubt that the perineal body serves many useful purposes, and that its integrity was essential to the preservation of the tone of the vaginal and vulvar outlet.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

MEETING HELD FRIDAY, JANUARY 8TH, 1909.

The President, Mr. JOHN LENTAIGNE, in the Chair.

THE TREATMENT OF EXTROVERSION OF THE BLADDER BY TRANSPLANTATION OF THE URETERS INTO THE RECTUM.

MR. C. ARTHUR BALL read a paper on the above subject. Having discussed the principal theories as to the cause of the condition, Mr. Ball gave an account of the various operative procedures that have been recommended, and expressed the opinion that the safest and most satisfactory procedure was the transplantation of the ureters into the rectum by an extraperitoneal operation. Details were then given, by means of lantern slides, of a case in which the operation had been carried out in a boy, æt. 5. The child was operated on last July, and the result was satisfactory. the child being in perfect health six months later, and having very tair powers of retaining urine in the rectum. Three months after the operation urine could be retained up to three and a half hours, and this control had continued to improve since then.

The President said the case was, so far as he knew. the first satisfactory one that had been done in Dublin, and illustrated the improvement which had been effected in dealing with an apparently hopeless condition. By the newer process, unusually short and safe treatment had effected far more improvement than any of the complicated efforts made before. He desired to know whether it had been proposed to infold the rectum at the point where the ureter entered it, so as to make it less likely to slip out, and give a broader field for adhesion on the part of the ureter. He congratulated Mr. Ball on the result.

Mr. Seton Pringle wished to know if there was any

trouble in keeping the peritoneum back, and seeing

what was being done?

Mr. BALL, in reply, said he did not think infolding of the rectum had been done. In his case there seemed to be no tendency to slip out. He did not see the peritoneum until he first came on the rectum. One would have expected it to get in the way sooner. than it did. There was considerable separation of the public bones, and the pelvic cavity was consequently very shallow, so that the case was ideally arranged for the surgical procedure carried out.

ABSCESS OF THE PANCREAS, WITH REPORT OF A CASE FOLLOWING ACUTE GANGRENOUS PANCREATITIS.

Mr. Seton Princle read a paper on the above subject. After expressing the opinion that all cases of pancreatitis should be reported, so that a fuller knowledge of the disease should be griefd by grained by griefd by ledge of the disease should be gained, he gave a de-

tailed acount of the case on which the paper is based.
The patient, æt. 46, with a marked alcoholic history,
was admitted to hospital on the twelfth day of his
illness with signs of peritonitis of the upper abdomen. where a large tumour mass could be felt. Operation was performed immediately, and a large abscess found in the lesser peritoneal sac, the edges of the opening into the abscess were sutured to the parietal peritoneum, and a large drainage tube inserted. There were numerous patches of fat necrosis in the omentum and a small quantity of bloody fluid in the larger sac of peritoneum. The patient progressed favourably for a few days, but gradually lost strength, and died on the twelfth day after operation. The urine, several days after operation, gave a marked Cammidge "C. reaction." At the post-mortem it was found that the reaction." At the post-mortem it was found that the head and body of the pancreas had sloughed, only the tail surviving; no gall-stones were discovered. Mr. Pringle then discussed the ætiology of the case, and expressed the opinion that the pancreatitis in his patient was the result of alcoholic gastro-duodenal catarrh. After enumerating the various forms in which suppuration may occur in the pancreas, he gave a short account of the methods of treatment at present employed, and concluded by calling attention to the fact that only some sixteen cases of operation for pan-creatic abscess were recorded in the literature.

The President said that cases of comparatively

newly-recognised diseases, the symptoms of which were most obscure, were just such as should be brought forward in detail in the excellent way in which Mr. Pringle had reported this case, and they were the more grateful to him for having brought forward a case in which his efforts to cure had not been rewarded with success. The case showed the importance of early operation. If the abdomen had been opened at an early stage it was possible that the gangrene might have been averted; at any rate it would have been more hopeful. It was only by the bringing forward of such cases that they would be able to arrive at an early diagnosis.

Mr. STOKES said he had seen a similar case operated on a couple of years ago, in which acute septic peritenitis was found at the post-mortem. But for that the case might have pulled through. The question of draining behind had been raised, but the Americans had given up that unless the inflammation were con-

fined to the tail of the pancreas.

Mr. BLAYNEY said there could be no doubt that at Mr. Blayney said there could be no doubt that at the time the patient was seen no surgical measures could have saved him. He thought it was of very great importance that these cases should be diagnosed in their very earliest stage. If the patient had been seen when he got the first pain, an operation then might possibly have been successful. Only by examination of a series of cases would they find some group of symptoms which would indicate the onset of the disease and for that reason he thought the publithe disease, and for that reason he thought the publication of such cases most useful.

Mr. Ball suggested that the apparently greater frequency of the disease in hospital patients than in private patients might arise from differences of habits

in eating and drinking.

Mr. Pringle, in reply, said that in his case there was no peritonitis in the lower abdomen. Cammidge had improved his reaction, and had obtained it in every case in which there was pancreatitis, either acute or chronic, and it was present in only four out of 150 cases in which there was no pancreatitis. It was, therefore, apparently a fairly satisfactory clinical test.

Mr. Wheeler being absent, his paper on "The Choice of Operation in Cancer of the Rectum" was

read by the Secretary.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD FRIDAY, JANUARY 15TH, 1909.

The President, Dr. A. J. WALLACE (Liverpool), in the Chair.

Dr. J. W. Martin (Sheffield), was elected President; Mr. M. H. Phillips (Sheffield), General Secretary; and Dr. W. K. Walls (Manchester), Treasurer, for 1909.

Professor Lorrain Smith and Dr. W. Fletcher

SHAW (Manchester) read a paper on the PATHOLOGY OF RED DEGENERATION OF UTERINE FIBROIDS. They had examined four specimens, three of which were associated with pregnancy. Staining by Weigert's fibrin method they found extensive thrombosis of the blood vessels in the red areas of all four specimens, and this they consider the essential and characteristic change. There was no evidence of recent or old extravasation of blood. The myomatous tissue was also in a state of atrophy and degeneration, being replaced by a homogeneous substance, which stained faintly with eosin. But this form of necrotic softening is very common in fibroids, and further observation is necessary to show whether red degeneration ever occurs apart from such a process of necrosis. Excess of fat, as droplets or crystals, was also found. Two of the patients had presented toxæmic symptoms, and in each of these cases the authors found an active leucocytosis and bacteria in the tumours; staphylococci in one and diplococci in the other. Neither bacteria nor a leucocytosis was found in the other cases. Finally, the authors pointed out that redness dependent upon Virchow's angiomatous degeneration may be present in such a degree that the tumour has considerable naked-eye resemblance to the true red degeneration.

Drs. Lloyd Roberts, Briggs, Donald, Walls, Fothergill,

Lea, Grimsdale and Croft discussed the paper, and Professor Lorrain Smith, in reply, expressed his opinion that the bacterial infection was probably secondary to and predisposed to by the thrombosis; that the excess of fat was dependent upon arrest of absorption resulting from the thrombosis, and that pregnancy, by mechanically hampering the circulation in the tumour, and the puerperium, with its increased coagulability of the blood, were possibly predisposing factors in the causation of red degeneration.

### CENTRAL MIDWIVES BOARD.

MEETING HELD THURSDAY, JANUARY 21ST, 1909.

Dr. CHAMPNEYS in the Chair, all Members being present.

#### THE NON-REPRESENTATIVE DEPARTMENTAL COMMITTEE.

THE CHAIRMAN read the following letter from Miss Wilson, announcing her resignation from the Board, which she had sent in to the Lord President of the Council last month:

To the Right Hon. Viscount Wolverhampton, Lord President of the Council.

My Lord,—I wish to place in your lordship's hands my resignation of the seat on the Central Midwives Board, to which I have been twice nominated by successive Lords President during the past six years.

The term of my second appointment does not expire till April, 1909, but I prefer to resign now in order to be free to protest against the constitution of the new Departmental Committee which your lordship has appointed to consider the working of the Midwives Act, 1902, and the supply and training of midwives, etc. That such a committee should have been selected without any notice given to at least one of your nominees on the Central Midwives Board is a matter on which your lordship is naturally the proper judge, but the absence of any proper certified midwife from the list of the committee has caused painful surprise to all who are familiar with the questions which will come under consideration. Many of these women are well-fitted by training and education to be of great service in the deliberations which form part of the proposed work. If your lordship could contemplate the appointment of a committee to investigate and report on the curriculum and supply of medical practi-tioners from which all doctors were excluded you would realise a parallel situation. The admission of the evidence of midwives as witnesses before the committee would be no equal substitute for the appointment of midwives on the committee itself. As President of the Midwives' Institute for the past 15 years, and as nominee of the Privy Council on the Central Midwives Board for the past 6, I feel it my duty, on behalf of the 26,000 women on the Midwives' Roll, to enter my earnest protest against an exclusion which is as unjust as it is unwise, and holding this opinion I find myself unable to sit any longer on the Central Midwives Board as your lordship's official nominee.

I have the honour to be, my lord,
Your lordship's obedient servant,

J. WILSON.

December 16th, 1908.

The following resolution was thereupon proposed from the Chair, and carried unanimously:—"That the Board learns with great regret of the resignation of Miss Wilson, who has been a member since its foundation, and desires to express its appreciation of her services, which have been invaluable, and which have involved an amount of self-sacrifice and devotion which only those who have worked with her can esti-They consider her loss irreparable."

REPRESENTATION OF GENERAL PRACTITIONERS. Mr. PARKER YOUNG proposed:—"That the Lord President of the Council be respectfully requested to consider the advisability of adding to the Departmental Committee representatives of the interests of general medical practitioners and midwives, as the Board consider that such additions would greatly enhance the value of the report eventually come to by that Committee." This was carried by 5 votes to 2.

Dr. STANLEY ATKINSON said that, as a Board constituted for the administration of the Midwives Act. he thought they had reason and right in making any suggestions which they thought would be beneficial to the working of the Act.

Sir George Fordham wished to point out that, should this request go before the Lord President and be refused, their Chairman, who was also a member of the Departmental Committee, might find himself in an embarrassing position.

Sir WILLIAM SINCLAIR remarked that it was not their place to dictate to the Privy Council, or to interfere with another Government department. He thought the

matter of fees to medical men called to the assistance of midwives might well be left to the Medical Press.

Mr. Parker Young denied that there was anything in the nature of "dictation" in his motion. As for interfering in matters outside their own business, he asked what was the business of the Board if it was not the working of the Midwives Act, and they all knew the Act, as it stood at present, was unworkable. This was proved again and again by the letters received from practising midwives, complaining that they had sent to seven or eight doctors in succession to come to their aid in difficulty, according to the Rules of the C.M.B., and not one of them would come. In the interests of the thousands of women who were attended by midwives, and who, to a great extent, were voice-less in these questions, he considered it their solemn duty to do everything in their power to render the Act more workable. And when a committee was appointed to consider such questions as the fees of medical men and the training of midwives, he considered it essential that these questions should be discussed by experts. The Chairman would be invaluable in a great many ways, but he was a consultant, and so was Sir William Sinclair, and they could not realise, as the general practitioner and the midwife did, where the shoe pinched.

The resolution having been carried, the Secretary was instructed to forward it to the Lord President of the Council.

The Report of the Standing Committee dealt with letters from the acting solicitor of Eliza Annie Collins, No. 8,000, promising to suppress the circular suggesting that she is qualified to give medical treatment.

There were several letters, from Dr. A. Stookes, of Liverpool, and others, relative to the caution lately impressed by the Board upon training schools and recognised teachers; that pupils must have made repeated vaginal and abdomnial examinations in the 20 cases before they could count, and inquiring how this was reconciled with Rule E. 8, which recommends few, if any, vaginal examinations. The reply agreed to by the Board was that the Rules applied to practising midwives, not to training schools and pupils. In reply to an inquiry from the Secretary of St. Mary's Hospitals, Manchester, as to whether this requirement of the Board was meant to be retrospective, the Board agreed that it was not.

The Newcastle-on-Tyne Hospital was approved as a training school, and the following were approved as a teachers:—F. H. Allfrey, M.B.; J. H. Robinson (Capt. R.A.M.C.), M.R.C.S., L.R.C.P.; Mary Ann Dacomb Scharlieb, M.D., and H. M. Stumbles, M.B.

### CORRESPONDENCE.

#### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.
Paris, Jan. 24th, 1909.

PALMO-PLANTAR SIGN OF T.F.

Some years ago attention was drawn to a special vellow colouration of the palms of the hands and the soles of the feet by a Russian doctor, which he considered as almost pathognomonic of typhoid fever.

A few months ago another doctor made a special A 1ew months ago another doctor made a special study of this question and came to the same conclusion. Out of 220 patients examined, the sign was present in 216, or over 98 per cent.

The colouration begins to appear in the first week

of the malady, and before the appearance of the lenti-cular spots. The colour, which at the beginning is crange yellow, deepens during ten days or so, and then remains stationary until the end of the disease. When convalescence sets in, the hands and feet desquamate, and the skin finally recovers its normal aspect. Where the fever was prolonged beyond the normal time, or terminated fatally, the yellow colouring crept over the sides and back of the fingers.

#### SURGICAL PHLEGMASIA

The usual treatment of external inflammatory lesions, as phlegmon, adenitis, mammitis, etc., is warm applications, and, when suppuration has set in, the bistoury; but an operation may be, however, frequently avoided by the application of a preparation of ichthyol and glycerin to the seat of the inflammation:

— Ichthyol, I oz.

Glycerin, 4 oz.
In a few hours the painful symptoms diminish considerably and soon disappear, while in many cases the progress towards suppuration is arrested.

#### HÆMORRHOIDS.

Hæmorrhoids are always more or less troublesome, but when the piles become congested and inflamed, they require prompt treatment. In such cases very warm enemas (113°) are advisable, as well as applications of hot water to the distended veins, while the following ointment will give ready relief:—

Stoyain, s gr.

Stovain, 5 gr.
Sol. of adrenalin (1-1,000), 20 drops.

Vaseline, 3 dr.
Internal hæmorrhoids will be treated with suppositories :-

Stovain,  $\frac{1}{3}$  gr. Ext. belladona,  $\frac{1}{3}$  gr. Cacao butter, q.s. LEUCORRHOBA OF YOUNG GIRLS.

Leucorrhœa in young children is frequently depending on a general lymphatic or anæmic condition. The treatment should consequently include preparations of arsenic, iodine, iron, etc. The local treatment consists in astringent hip baths and external lotions to the parts twice a day with—

Alum, 1 dr. Sulph. zinc, 1 dr.

Water, I quart.
Generally this treatment is sufficient to effect a cure, but sometimes it may be necessary to inject into the vagina by means of a small syringe a solution of permanganate of potash (5 gr. to a quart of boiled water), and to cauterise the labit with a solution of nitrate of silver (1 in 50).

### GASTRIC VERTIGO.

Dizziness in the head is generally of gastric origin, and can accompany every form of dyspepsia. The vertigo is observed on rising from bed in the morning, or one hour after meals. It gives the patient the aspect of a drunken man, and is due to an excess of acid in the stomach. The prognosis of the affection is benign, as by appropriate treatment a cure is speedily obtained

Dietetic regime is very important. According to Prof. Robin, these patients have their stomachs more or less distended, and consequently rules of eating should be observed. In the morning the patient will take some toast, an egg, and some cooked fruit; at mid-day, meat without sauce, eggs in the shell, vegetables without grease, while only a little pure water is allowed. After meals a cup of hot tea. Coffee and tobacco should be suppressed, as well as alcoholic drinks.

The medical treatment is not very complicated. quarter of an hour before breakfast the patient should take a wineglass of quassia infusion, and before dinner 6 drops of tincture of nux vomica. After each meal one of the wafers :-

Calcined magnesia, 8 gr. Bicarb. of soda, 8 gr. Prepared chalk, 6 gr.

If much flatulence be present, a tablespoonful of— Fluoride of ammonium, 6 gr.

Water, 10 oz.

At the moment when the dizziness is about to be felt, it may be warded off by a tablespoonful ofBromide of potassium, 11 dr. Cherry laurel water, 2 dr. Syrup of ether, 1 oz. Inf. of valerian, 4 oz.

Where the vertigo is suspected to be also in relation to existing arterio-sclerosis, small doses (2 to 3 gr. a day) of nitrite of soda will rapidly improve the situation by diminishing the tension of the blood.

#### PHLEBITIS.

Besides the usual immobilisation in a box splint lined with cotton wool, the application of the following ointment is very efficacious:

Collargol, 30 gr.

Vaseline, 3 dr.
Or, better still, injections each day of electragol (1 dr.), parallel to the vein without touching it. Rapid

### GERMANY.

Berlin, Jan. 24th, 1909.

AT the Medizinische Gesellschaft Hr. J. Hirschberg

THE TURRET OR DOME SKULL.

His observations were made in reference to a case observed last summer, that of a female who had this peculiar deformity of the skull. She was 18 years of age, and it was stated that up to her fifth year the sutures of the skull had remained open; from her earliest youth she had been subject to convulsions, which gradually became less frequent. Nothing was to be remarked in her family history. Her intelli-gence was normal. From her eleventh year she had disturbance of vision, which had remained unchanged since that time. The power of vision was about onethird, the field being contracted concentrically on both sides. There was advanced bilateral atrophy of the papillæ. The girl had a classical turret skull. Since the first publications on this subject (Graefe, Michel), the first publications on this subject (Graefe, Michel), this peculiar condition had been observed. The speaker had seen seven cases himself, six of them males, and all young, so that in accordance with statements met with in literature it appeared as if these individuals did not reach a great age. The skull was always narrow and high, which was generally due to early closing of the cuttures: there was simply to early closing of the sutures; there was simultaneously irritation or inflammation of the membranes of the brain, which through pressure caused atrophy of the visual nerves. There was no congenital syphilis in any case, but frequently traces of rickets. If such a child came under observation early it had been proposed to trephine, in order to equalise the intracranial pressure, and in one case this had been carried out with success. This success indicated that it was not a narrowing of the foramen that caused the pressure

and the atrophy of the optic nerve.

Hr. Grunmach showed Röntgen illustrations of turret skulls, and gave a careful description of them.

Hr. Heubner related particulars of a family with twelve children, two of whom were exquisite illustrations. trations of the deformity, and became blind within 14 days; a third child had micromelia, in consequence of chondrodystrophia fœtalis.

Hr. Hollander suggested a careful examination of the Inca skulls, in which this deformity was brought

about by artificial means.

At the Ophthalmological Society Hr. Leber gave an

address, entitled
Investigations into the Ætiology of Trachoma. These investigations were carried out at the instance of the Kultus Minister in Trieste. In numerous illustrations he showed the familiar granules in the epithelial cells of the trachomatous subject, which had been considered by some authors to be parasites, and as such connected with the ætiology of the affection. The speaker had so far altered the mode of investigation, that for fixing he had made use of the moist sublimate fixing material, that Schaudinn had used in investigations into the protozoa; the only new observation he had made was that he had found these granules on or within the red blood corpuscles.

Hr. di Santo made the statement that, in his trachomatous apes and also in the human subject, he

had met with the granules in the subconjunctival connective tissue.

Hr. Herzog remarked that the figures shown were but little different from those of inflammation in non-trachomatous cases, and showed illustrations in support of his statement; they very much resembled trachoma granules.

The Deutsche Med. Zeitung, 4/09, has a communication on the subject of

WET NURSES.

Drs. E. and L. Oberwarth, who have been for many years connected with a home for wet nurses, have come to certain conclusions with regard to their engagement, etc., that possess a considerable interest. They are shortly as follows:—In the interests of her child no mother should be allowed to hire herself out as a wet nurse before her own child is six weeks old and weaned. When the father cannot be approached she should pay the costs of the keep of her own child out of her wages, but the party engaging her is under obligations to see that this is punctually carried out. In case of illness it is the duty of the parties employing her to pay part of the increased cost of the child's maintenance. The termination of a wet nurse's engagement should be subject to a fortnight's notice on either side.

### AUSTRIA.

Vienna, Jan. 24th, 1900.

TUBERCLE AND SPLENECTOMY.

ALBRECHT exhibited a female patient, æt. 37, on whom he had operated for isolated primary tubercle of the spleen. The organ when removed weighed 1,370 grm., or nearly 3 lbs. It was rich in fibrous tissue and throughout bestrewn with miliary tubercle. No and throughout bestrewn with miliary tupercie. No other part of the body bore any indication of a tuber-cular process. Schwartz gave a brief history of the case and the blood analysis. Before the operation he found the hæmoglobin 67, with Fleischl's instrument, the red blood corpuscles 4,500,000, with an increase of the transformation form in the white blood corpuscles to the part cent, while the exceptability were a puscles to 13 per cent., while the eosinophile were 2 per cent. After the operation the hæmoglobin was 65, with the same instrument, the red blood corpuscles unchanged, while the transformation form was 11 per cent., and the eosinophile 4 per cent. The patient now appears to be in good health.

ANEURYSM OF THE BASILAR ARTERY.

Wiesner showed a few anatomical preparations of saccular aneurysms which he had collected, taken from the basilar artery. These aneurysms had all split the pons varolii, which deformed the right half of that structure, as well as the medulla oblongata. Chvostek gave a full clinical description of one of the cases that Wiesner exhibited. The patient had always been per-fectly healthy up to the beginning of last year, when he first complained of headache, which was followed by vomiting and vertigo. He gradually lost his by vomiting and vertigo. He gradually lost his hearing and sight, with difficulty in swallowing, double vision and imperfection in speech. After this paresis of the right side of the head, paralysis of the right abducens and internal muscles, while paresis was observed in the left abducens. The same condition existed in the uvula, but the paresis was slight on the left side of the body, with increased reflex. The papillæ were not congested or enlarged, but the associated paralysis and the freedom of the motor nerves from disease pointed to some centre of disturbance in the pons which was assumed during life to be tuber-

CUTANEOUS REACTION WITH TUBERCLE.

Monti gave the members a short account of Pirquet's reaction and various modifications that had been performed. He said the scarification of the skin and the reaction obtained from tubercle were often very different. He thought this varying result was due to the imperfect introduction of the toxin, which often led to a characteristic cutaneous reaction. Lignières had performed experiments in this direction by shaving a part and then rubbing the tuberculin into it; reac tion in this case was constant and specific, always giving a lupus change as the result. Lautier in a similar manner within 48 hours obtained on the skin of a tubercular individual, with a 1 per cent. solution,

a vesicular efflorescence, each vesicle having an inflammatory base. This reaction has the disadvantage of being less sensitive as its results cannot be obtained before 48 hours, yet it has the advantage of vaccination in avoiding much local disturbance. More endeavoured to obtain similar results by rubbing a 50 per cent. tuberculin ointment into scrofulous children and obtaining a specific result. On the site of the part rubbed fine nodular inffloresences were produced, which gradually disappeared in a few days.

Monti now gave his own experience on 300 children. Moro's ointment, he said, was a specific because all the cases, when used cutaneously or percutaneously, had a positive reaction, but the percutaneous, he might say, was less sensitive than the cutaneous vaccination. Monti then showed the effects on several children whom he had under examination, and demonstrated from others. Tedeschi's auriculo-reaction is to inject the toxin into the lobe of the ear, and induce infiltration of the subcutaneous cellular tissue. This reaction is similar to Hamburger's stabbing form, but has the disadvantage in ambulant patients of producing swelling of the retro-auricular glands. recommends cutaneous vaccination, controlled by the stabbing reaction, but where this is objected to, Moro's ointment is to be recommended. Escherich thought the stabbing method was the surest for tubercular diagnosis, and asked whether Monti used bovine or human tuberculin? Monti replied human was used.

### FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.
SCOTTISH UNIVERSITY WOMEN'S SUFFRAGE SOCIETY. -At a representative meeting of the committee of women graduates of the Scottish Universities, held in Edinburgh on January 16th, it was decided to form a suffrage association on a non-party basis. The main object of the society is sufficiently implied in its title; it proposes to attain its object by an active propaganda. Meetings in favour of women's suffrage are to be held in every town and village in Scotland; petitions are to be sent to Parliament from every such meeting; a general canvass is to be carried out; statements are to be asked from Members of Parliament and Parliamentary candidates of their views; suffrage organisers are to be obtained in every constituency; suffrage literature is to be compiled and distributed; debates are to be encouraged-in short, every form of recognised constitutional agitation is to be adopted. Membership of the society is open to women graduates, and women on the Medical Register; others in sympathy with the movement will be welcomed as associates.

EDINBURGH PARISH COUNCIL AND THE INFIRMARY ASSESSMENT.—At the last meeting of the Council an application from the Infirmary for relief from assessment was considered, and rejected on the ground that Act to exempt the institution. One member of the Council expressed the opinion that, in view of the relief which, in one way and another, the Infirmary gave to the rates, the Council should send a donation to the funds of the institution. Another speaker said the Council should not contribute unconditionally; they wanted a quid pro quo. A committee had been appointed to confer with the Infirmary regarding the establishment of wards for the treatment of temporary mental disorder, and if these were opened they would recognise the relief afforded to the rates by a suitable donation.

EDINBURGH DISTRICT LUNACY BOARD.—According to the report of Dr. John Macpherson, Commissioner in Lunacy, the Bangour Asylum now houses 747 patients. and there are now only about 100 vacant beds. At the present rate of increase the available accommodation will soon be filled, and there are still roo patients in the Royal Asylum for whom provision must be made within two years. The accumulation of the asylum population can to some extent be controlled by preventing the admission of unsuitable cases, and by removing to private dwellings patients for whom asylum

treatment is no longer necessary. The boarding-out system, therefore, must be extended, but it is estimated that nearly one-third of the patients in Bangour are physically infirm and senile; so that the number from which suitable cases can be selected is limited by that amount. Judging from the growing tendency manifested during recent years in Scotland to send old and infirm persons to asylums, Dr. Macpherson commends to the consideration of the district board the question whether future additions might not advantageously take the form of simple and inexpensive infirmary accommodation.

#### **BELFAST**

ULSTER MEDICAL SOCIETY .- On Thursday evening last a most successful smoking concert was given in the Medical Institute, Belfast, by the President of the Ulster Medical Society, Mr. T. S. Kirk. The guests were received by Mr. and Mrs. Kirk in the library, and, after tea and coffee had been served there, they proceeded to the large hall, in which a capital smoking concert took place. Dr. MacIlwaine, Mr. R. J. Johnstone, and Mr. Waugh contributed several items, Mr. Lloyd Campbell told some stories, and the members of the Northern Male Quartette and several others took part. During the evening Mr. Kirk announced that the Society had unanimously decided to confer its Honorary Fellowship on Sir William Whitla, in recognition not only of his professional attainments, but also of his many acts of kindness to the Society, including the building and equipping of the home in which the members were then met. He concluded by presenting to Sir William Whitla a certificate of members were bership, illuminated on parchment and ornamented with beautifully painted miniatures of the Institute, and of the Smyth Memorial window in it. Sir William, who was completely taken by surprise, replied in a few words.

### LETTERS TO THE EDITOR.

THE APPENDIX: ITS USE, ABUSE, CLAIMS FOR PROTECTION. ABUSE, AND ITS

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—As soon as I saw in the daily Press a reference to my recently read but not fully published paper on the appendix, I consulted a friend holding one of the very highest positions in the surgical profession. first advice was, "Do nothing." I agreed with I agreed with him; but, at the same time, I pointed out that twenty times as many medical men would form their idea of my paper from the brief but misleading notice in the lay Press as would read my paper itself. And now we have a surgical teacher so universally esteemed as Professor William Rose, in criticising my views, actually stating that his knowledge of them is gained from the Daily Mail! But the remarkable thing is that, not only Professor Rose, but other surgeons who have been content to get their information on the subject from the newspapers, have not been careful to read even them correctly. I never suggested that "the appendix should be detached in certain cases" "to wander at will through the intricacies of the general peritoneal cavity"—quite the contrary.

With much that Mr. Rose says I agree—e.g., that

"we never hear in the lay Press of the failure of" remedies and manipulations. I felt strongly the omission of the lay Press to state that my surgical brethren were to a great extent not in agreement with me—that, in fact, the question was still *sub judice*. However, the *Pall Mall Gazette* did something to redress that by printing an abstract of the discussion on the paper. Professor Rose concludes with a most apt quotation from Sir William Jenner:—"It is the duty of the physician (including, of course, the operating surgeon and the general practitioner) to prevent disease," "and, failing that, to alleviate suffering and prolong life."

It is with the object of preventing one of the most terrible diseases known—septic peritonitis—that I advo-cate the transference, in selected cases, of the appendix from the peritoneal cavity to the abdominal wall. My published cases show what this can do to "alleviate

suffering," and there is even a possibility, having regard to Metchnikoff's well-known views, that it may tend to

prolong life."

It is evident also that your correspondent, "M.B., M.S." (MED. PRESS, Jan. 20th, 1909, p. 67), has also not read my paper, or even Sir William Macewen's address on the functions of the appendix, or other before making up his mind about the questions under discussion. When the appendix is properly transplanted into the abdominal wall, and any stricture, twist or kink of its proximal part removed, the result is not to "allow permanent escape of its lubricating secretions." Surgeons do have to cut down on the appendix in cases where they cannot make themselves "as certain as possible that pathological changes calling for its removal exist." And it is quite misleading to say that, "If the appendix on exposure should be found healthy, it would be left intact; if diseased, it would be removed." Hundreds of really or apparently intact appendices have been removed by surgeons even of high reputation for experience, character, and judgment. No one can be more reluctant than I to remove an appendix which is apparently healthy; but there are diseases of the appendix which only the microscope can reveal, and there are cases in which, while the appendix looks healthy, the history tells the surgeon that it has been diseased before, and may be diseased again. When in this dilemma, I have felt the greatest comfort from being able to preserve the appendix, and at the same time to transfer it to a place in the abdominal wall, where an attack of appendicitis will not be attended by the dangers of peritonitis. "M.B., M.S." is right in agreeing with you that "we

must free our minds from cant in regarding that great institution, the British Press." But that does not mean that we are to scold it. The journalist who first set alight the flame of publicity as regards appendicostomy in the lay Press went to the West London Hospital for information. The Secretary telephoned to me, and I, of course, had to reply that I could not give him any information. He then appears to have applied to some other medical man—I do not know whom—who was, perhaps, as good-natured as my friend Professor was, pernaps, as good-natured as my friend Professor William Rose, and equally vague in his ideas about appendicostomy. It was not the fault of the lay Press that their first references to my paper were so misleading (so particularly trying to me, I may add, because they represented my views as being the exact opposite of what they really were). As soon as my paper appeared in full, the lay papers corrected the worst mistakes which they had formerly made.

The following questions arise (if we are really going

The following questions arise (if we are really going to "divest our minds of cant"):-

(1) Is the public, or a large segment of it, interested in the progress of medicine?

(2) If it is, can any power on earth prevent the newspapers from endeavouring to keep it informed on such matters?

(3) Then what steps can medical men, or medical institutions (including the medical journals) take to ensure that medical paragraphs and articles in the lay Press shall be accurate, shall distinguish between what is controversial and what is accepted, and shall prevent the publication of living medical men's names?

I offer no answer to these questions myself—at all events just now. What I am concerned with is to persuade your subscribers to read my paper itself, and, above all, the 36 case reports which form the real substance of it. The theories and hypotheses to which my critics have almost entirely confined their attention were mostly put forward by me long ago, in the Cavendish Lecture for 1907 and elsewhere.

I am, Sir, yours truly,

C. B. KEETLEY.

Grosvenor Street, January 20th, 1909.

A FORGOTTEN PROFESSION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—We are informed by posters large, that, thanks to a Liberal Government, old-age pensions were paid on January 1st, 1909. I am no politician, but it appears to me that this poster should rather read: "Thanks to the self-denial of the middle classes, who have always to pay the piper, but who are never

allowed to choose the tune." We have in power at the present time a Government, numerically strong, but some of us are inclined to think mentally weak. The one object of this Government is to diminish the hours of labour and to increase the pay. Through an hours of labour and to increase the pay. Inrough an oversight, doubtless, the most sweated and worst paid profession has escaped the vigilant eye of our legislators, and in order that the Government may not be blamed for this inadvertent omission I would draw the attention of your readers to several points which might interest their local M.P.s.

1. Midwives Act.-Provision made for the patient obtaining the services of a medical man in case of difficulty. No provision made for paying his fee.

2. Birth Notification Act.—The duty of notification in certain cases falls upon the medical attendant. No fee; but a fine in the event of the medical man failing

3. Medical Inspection of School Children.--Provision made for ascertaining mental and physical defects. No provision made for remedying them. If such children go to a local hospital, sweating of the hospital staff is the result.

4. Death Certificates.-No fee.

· I am, Sir, yours truly,
A Provincial Practitioner.

Bedford, January 22nd, 1909.

THE INEBRIATES' ACTS COMMITTEE AND DRUG CURES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—It seems to me a matter for regret that the Committee whose Report you have just examined in two able leaders did not find it possible to deal in plain terms with the question of quack drug cures. An enormous service to the public would have been done merely by publication of analyses of the medicines employed in the most bepuffed of these cures. Some of them contain no ingredient of any potency whatever; a good many, especially those hailing from the United States, contain nothing but alcohol. Authoritative publication of such facts would alone have struck a heavy blow at a great system of injurious imposture, and would, perhaps, have induced innocent lay supporters of some of the cures now carried on under the cloak of philanthropy to consider their position and to listen to reason. As it is, the curt, ambiguous, or even equivocal terms in which the Committee dismiss the subject, are calculated to confirm the opinion of the uninitiated that there is "something in" the claims to miracle working which are put forth by most of the proprietors of drug cures. It should surely be possible to prove, even to people totally ignorant of science, if commonly intelligent, that alcoholism is not a simple condition due to one and the same cause, that its causation is extremely complex, being made up of various distinct physical, mental and moral causes. In one case, merely mental or physical depression may have led the patient to find a solace in drink, or he may have been led on through trust in one of the sham tonics containing alcohol, now so enormously advertised. In another case the cause may be moral obliquity developing from childhood, a condition where example and habit have produced a low character, in which alcohol to excess affords the sole enjoyment in life. There is then the hardened sot, whose brain and nervous system have undergone alcoholic degenerative changes, with actual destruction of tissue elements, changes always accompanied by corresponding loss of will power and in-ability to resist the temptation to drink. To cure alcoholism in any of its numberless phases merely by the administration of drugs would constitute a miracle something like the exorcising of a demon of the olden days. The pretence at secrecy in most of these cures is alone enough to condemn them. The discoverer of a simple remedy for drunkenness would rank with the greatest benefactors of mankind, with Jenner, Pasteur. Lister. Wealth and fame would surely be his. All be would need to do would be to demonstrate the quality of his remedies before a competent scientific tribunal. That the pretences of unqualified drink doctors are accepted by large numbers of "educated" men is not wonderful when we recollect that "educa-tion" in our great schools and colleges virtually

excludes science, and often actually leads the "cultivated" graduate to distrust, scorn, or hate science and the scientific method. This is one of the factors helping to lead our country to disaster in matters of more vital importance than bogus drink cures; and so the pessimist may ask—why trouble about so trivial a detail as the saving from destruction of a few more or less among the masses of an already degenerate and falling people?

I am, Sir, yours truly,
MEDICAL TEMPERANCE REFORMER. January 21st, 1909.

#### THE SCOTCH OATH.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—As you say in an editorial note in your last issue, judges, magistrates, and coroners are uniting in an effort to induce witnesses to swear according to the Scottish fashion, instead of as was formerly the case uniting to brow-beat the unfortunate wight who elected to use his legal privilege of doing so. This being so, it seems to me as if the time was propitious for all bodies interested in preventive sanitation to follow the legal example and endeavour to diffuse a knowledge of the dangers of the present insanitary practice. It is common at the present time to place in public dis-pensaries, and such places, large notices calling attention to the dangers of spitting, and to the simple measures which can be taken to prevent the spread of tuberculosis. I venture to suggest that bodies, such as the Sanitary Association and the Women's Health League in Dublin, and kindred bodies throughout the United Kingdom, should endeavour to obtain permission to place posters in all the Courts calling attention to the dangers of "kissing the book" and advising witnesses to adopt the Scotch oath. I am sure the legal authorities would facilitate the exhibition of the poster, and, if it was systematically exhibited for some six months it would do more to stop the present practice than any amount of occasional advice. It is obviously impossible for a judge to warn every witness specifically of the danger he or she is running by kissing the book, but by allowing the posting of a large notice in his court the same end would be even more successfully attained.

I am, Sir, yours truly A MEDICAL WITNESS.

January 23rd, 1909.

THE STANDARDISING OF DISINFECTANTS. To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Absence abroad has till now prevented my noticing the combined attack of three trade rivals which has been appearing in the columns of various medical and sanitary journals during the past two or three weeks, professedly arising out of the suggestion recently put forward by Dr. Rideal and myself in connection with the test introduced by us five years agoa suggestion which, I hasten to add, was made at the earnest request of certain prominent Medical Officers of Health, with the object of calling attention to the need for standardising, a condition which is now imposed in the "tender forms" of many of the leading

authorities dealing with the question of subsidence.

Jeyes' Sanitary Compounds Company have already, in the above-mentioned columns, expressed their readiness to adopt any better test that may be produced than that above referred to, so I may for the present dismiss that point. But I do protest against the introduction of personalities and deliberate attempts to distort facts.

It is within the knowledge of these correspondents that the Rideal-Walker test was published two years before I was appointed managing director of Jeyes' Sanitary Compounds Company, and vet again and again my present position is harped upon in order to suggest that the test was devised to suit, and unfairly favour, Messrs. Jeyes' preparations. The intention is obvious

A glaring example of the other method I complain of may be seen in Mr. Kingzett's letter in your issue of December 23rd, 1908. There, choosing to ignore the modification introduced by Dr. Sommerville and myself (a) to meet such cases as may call for the use of

special diluents, he calmly compares the effect of a preparation of his own in the presence of sea water with that produced by one of my company's prepara-tions (also in sea water), the labels of which state that "the fluid will not mix with brackish or sea water," suppressing the fact that where such conditions exist we put forward a special preparation made to meet this particular requirement, and bearing a label to this effect. This fact is well-known to Mr. Kingzett, and, though one may grow accustomed to encountering such manipulations in trade circulars, it argues both great confidence and a curious idea of your readers' know-ledge and common-sense to use your columns for similar methods. As is well-known to Mr. Kingzett, the original test did not seek to embody any special conditions, but simply compared the relative value of various disinfectants in pure water; the modifications have followed, naturally and necessarily, in the effort to meet particular and varying requirements, and are intended for use only at the call of the consumer.

As to his parting sneer at the idea of allowing a mixture of emulsified disinfectant with water to stand

24 hours before use, I will not be so unjust as to credit him with a quarter of a century's ignorance of a

common hospital practice.

In conclusion, Sir, I desire to say that the test and its modifications represent honest attempts to grapple with a serious and difficult problem in a scientific manner, in the interest of the consumer, first of all, and next, not in that of one firm only, as has been insinuated, but of all manufacturers who have the same interest at heart. The fact that a large number of rival preparations, including some manufactured by the three firms referred to, already conform to the conditions proposed, might have suggested even to them that the object we had in view has been achieved. I am, Sir, yours truly,

J. T. AINSLIE WALKER.
Jeyes' Sanitary Compounds Company, Limited,
64, Cannon Street, London, E.C., January 18th, 1909.

### A DISCLAIMER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—At the request of the Stratford Branch of the British Medical Association, some few weeks ago I read a paper entitled "Medical Evidence and the Laws Relating to Compensation for Personal Injury. short time afterwards the editor of a medical journal wrote asking permission to publish the paper, and I

In the article I took occasion to deprecate the increasing prostitution of medical evidence, which, as you are aware, is confined to an infinitesimally small proportion of the profession.

I have been greatly annoyed to see in the daily press certain isolated quotations from my article, which without the context are calculated to give a wholly unfair view of the position.

The object of this letter is to state that I have taken no part in the publicity given to the article, nor was it done with my sanction, and that—while I am anxious that those who lay themselves open to the charge of unfair dealing should be exposed—the lay Press is, under no circumstances, the medium that I should have voluntarily chosen for this purpose.

I have communicated with the Office of the journal concerned, and am assured it has in no way been in

communication with the lay press.

The address, which was delivered in the East End, was favourably received by members of the profession present.

I am, Sir, yours truly, R. J. COLLIE.

Porchester Terrace, 19th January, 1909.

At the last quarterly meeting of the Council of the Royal College of Surgeons on January 14th, Mr. Henry Morris, President, in the chair, a formula for a new by-law relating to the admission of women to the examinations for the diplomas of Fellowship and membership, and of the License in Dental Surgery, was submitted.

### SPECIAL ARTICLES.

IRISH AND SCOTCH ASSOCIATIONS AND HOSPITAL APPOINTMENTS.

On the 21st inst. a conjoint meeting of the Irish Schools and Graduates and the Scottish Medical Diplomates' Associations was held at the Hotel Cecil, at four p.m. The object was to consider the exclusion of candidates not holding the higher diploma of two favoured English Colleges from most of the London and many of the provincial hospital posts. Sir Charles ball took the chair. The first resolution was proposed by Dr. Macnaughton-Jones, seconded by Dr. Horne, President of the Royal College of Physicians of Ireland, and carried unanimously. It ran: "That the present exclusion of all persons who do not hold certain qualifications from candidature for honorary positions on the staff of a public hospital is contrary to the public weal, and is a restriction which is not to the interest of the institution itself, excluding as it does all other candidates who may have exceptional claims to fill such positions." The second resolution, to the effect "That the advertisements in the columns of the lay press that honorary offices in certain hospitals are open only to those holding the Diplomas of some particular Corporation gives to the public the impression that such restrictive regulation is justified by the exceptional character of such qualification, which is not in accordance with fact." This was prowhich is not in accordance with fact." This was proposed by Dr. David Walsh, seconded by Dr. McManus, and carried unanimously. Mr. Lentaigne, President of the Royal College of Surgeons of Ireland, Surgeon-General Sir Thomas Gallwey, C.B., Sir Charles Cuffe, K.C.B., Dr. J. J. McCann and others supported the resolution. Among those present were: Mr. P. J. Freyer, Drs. G. Vere Benson, Fitzgerald Powell, J. G. Fitzgerald, Percy Lewis, A. Harries, G. N. Macnaughton, McMunn, Campbell Boyd, G. W. Dawson, Sydney Stephenson, R. J. Young, and others.

In the evening a dinner was held at the Hotel Cecil. Guests were received by Sir Charles Cuffe, K.C.B., President of the Irish, and by Dr. David Walsh, President of the Scotch Associations. Among the guests were: Sir Charles Ball, Mr. Lentaigne, Dr. Horne, Mr. S. G. Kirkby Gomes, Dr. Mouillot, Ccl. W. H. Thornhill, Col. James Moorhead, Mr. Swinford Ed-

Thorrhill, Col. James Moorhead, Mr. Swinford Edwards, Dr. Phineas Abraham, Dr. Creasey, and others, some of whose names have been mentioned above as present at the afternoon meeting. Professor J. Glaister, President of the Faculty of Physicians and Surgeons of Glasgow, was unfortunately prevented at the last moment from attending the meetings. At the close of the dinner a hearty vote of thanks was accorded to the Hon. Secretaries, Drs. T. Hobbs Crampton and P. H. Parsons, for the great personal labour and enthusiasm which had been thrown into the organisation of the

conjoint movement.

### REVIEWS OF BOOKS.

ANATOMY OF THE BRAIN AND SPINAL CORD. (a)

This voluminous and elaborate guide to the anatomy of the nervous system must surely rank as "high water mark" in monographs. It is intended both for students and practitioners, though it will probably be more resorted to by the former than by the latter. The illustrations, close upon 130 in number, 33 being printed in colours, have been drawn with the greatest care and really go far to elucidate the text.

The subject matter is presented in the order that it comes under the observation of the dissector, and, when necessary, explanatory embryological data are given to assist the student to understand the adult One special object in the work has been the location of functional centres and the tracing of their apparent, associative and efferent connections, so that throughout function goes hand-in-hand with structure.

The nomenclature is that of the B.N.A., but the English equivalents of the Latin terms have been largely employed.

(a) "Anatomy of the Brain and Spinal Cord." By Harris E. Lantee, M.D. Ph.D., Professor of Anatomy, University of Illinois and Jenner Medical College, Chicago. Fourth Edition. London: Sidney Appleton. 1908.

### RECENT MEDICAL LITERATURE. Summary OF ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

Treatment of Syphilis at Rochester Row Military Hospital.—Captain Hayes (R.A.M.C. Journ., January, 1909) gives a synopsis of the method of treatment of this disease as carried out at the Rochester Row Hospital. The treatment by intramuscular injections is considered best adapted to the needs of the service. Either calomel or metallic mercury injections are usually used, the preparations being those known as Lambkin's creams. The following is given as a general guidance for these injections: -Six weekly injections; four of calomel, agr. in each injection, and two of metallic mercury, i gr. in each injection. Two months' rest, and to attend fortnightly for inspection. Four fortnightly injections; amount of metallic mercury, 4 gr.. Four months' rest, and to attend as before. Four fortnightly injections; amount of metallic mercury, 4 gr. Four months' rest, and to attend as before. Four fortnightly injections; amount of metallic mercury, 4 gr. Six months' rest, and to attend as before. Four fortnightly injections, amount of metallic met-cury, 4 gr. Total length of treatment two years. In a great number of cases active symptoms have disappeared by the third calomel injection, when metallic mercury is substituted. The following instructions are issued to all concerned in the treatment of the case, and to the patient himself:—"(1) Weight to be taken weekly and to be recorded on the case sheet. (2) Urine to be tested weekly and record taken. (3) Teeth to be brushed after each meal, tooth-powder being supplied free to each patient. (4) The mouth-wash supplied to each patient to be used frequently. Two mouth-washes are used in this hospital, one a combination of lead acetate and alum sulphate, and the other a simple potassium chlorate solution. (5) Each patient to spend as much time in the open air as exigencies of the ward routine permit. (6) Each patient is to take a hot-air bath at least every second day, in which he will remain not longer than five minutes; the baths are only to be taken under the personal supervision of the wardmaster or his representative." Each case is carefully watched, and if it does not respond to one kind of injection another is tried. Calomel injections give the best result in the early symptoms of the disease. Soamin is excellent where there is much ulceration of the mucous membranes, and in cases with condylomata. Arsacetin is similar in action to soamin, but appears particularly useful in clearing up early skin lesions. It has the great advantage that it need not be prepared fresh daily as must be done with soamin.

Magnesium Sulphate in the Treatmont of Tetanus .-Miller (Amer. Journ. Med. Sciences, December, 1908) records a successful case of the treatment of acute tetanus by subarachnoid injections of magnesium sulphate. In all, ten injections were given, 2.5 cc. of a 25 per cent. solution of magnesium sulphate were injected into the spinal canal by means of a lumbar puncture. After each injection there followed promptly a paralysis of the legs, abdominal walls, sometimes the arms, while the neck and masseters usually escaped, and the muscles of the face practically always escaped. This paralysis appeared within thirty to sixty minutes, and varied in duration from eighteen to twenty-nine hours. Retention of urine was the rule, and it was necessary to catheterise the patient for nine days. No purgative effect was noted from the magnesium absorbed. The chief danger in the use of intraspinal injections of magnesium lies in its direct depressing influence upon the respiratory centre, this effect was produced repeatedly. The first injection produced no apparent effect upon respiration, nor did the third, which consisted of a smaller dose and of less concen-

tration than usual (2 cc. of a 16.6 per cent. solution), and was thus possibly too small to affect the respiratory centre. After each of the other injections, however, there was a more or less marked drop in respiratory rate, which was accompanied by a decrease and irregularity of amplitude; this change was of eleven to fourteen hours' duration, and in some instances alarming, notably after the second and fourth injections, when the rate dropped to seven and five per minute respectively, and necessitated constant watching and preparation for immediate artificial respiration. In spite of this respiratory collapse the circulation remained in good condition, there was no cyanosis, and the pulse remained regular and steady throughout. Miller gives the record of fourteen cases of tetanus treated by magnesium sulphate. Of eleven cases treated by subarachnoid injections five recovered, a mortality of 55 per cent.

Malignant Disease of the Ovary.-Gardner and McCleary (Surg., Gyn., and Obst., December, 1908) report eight cases of malignant disease of the ovaries. They remark that malignant tumours of the ovary are not only common, but they are of great variety. The relative percentage of malignant tumours to all tumours of the ovary has been variously estimated by different observers. Kelly puts it as low as 8 per cent., Leopold as high as 23 per cent., and Werder at 25.3 per cent. Of the eight cases recorded here, one was hypernephroma, one endothelioma, two carcinomata originating in adenocystomata, one carcinoma originating in papillocystoma, one adenocarcinoma, probably metastatic, and two varieties of sarcoma. The case regarded as metastatic was regarded as such apparently because the disease was bilateral, and Bland-Sutton has stated that bilateral carcinoma is secondary. In the present case no primary focus was discovered, and we find no valid reason in the account given for regarding the case as other than primary carcinoma.

Appendicitis and Leucocytosis.-Mitchell (Brit. Med. Journ., January, 1909) publishes a record of personal experience of the relation of leucocytosis to appendi-He found that in practically all cases of appendicitis and of acute abdominal or pelvic inflammation going on to pus formation or necrosis, there was an increase in the number of leucocytes. Speaking generally, the greater the increase the more scarce the lesion and the graver the prognosis. An exception to this was found in severe cases of sudden onset, in an individual whose powers of resistance were slight. It was more important to know the rate at which the leucocytosis was increasing than to know the actual count of leucocytes. A differential count was even more instructive than an absolute count. The noticeable change was an increase in the number of polynuclears, with a relative decrease of lymphocytes and eosinophils.

Alto-frequent Cytolysis of Cancer.-Under this title, Dr. J. Rivière, of Paris, has published (Annales d'Electrobiologie et de Radiologie) a critical study following up his communication on the same subject to the International Congress of Medical Electrology and Radiology, Paris. In his former communication, Dr. Rivière spoke of the cytolytic action of high frequency sparks on the cancerous cell, and of the necessity of employing these same sparks and effluves in the raw strgical wounds (brèches-opératoires) of malignant tumours, to disinfect and drain them, in order to prevent recurrence. He added that this special mode of application of electricity appeared to be, at the moment, one of the only therapeutical means to be tried in cases of inoperable tumours. The word "ful-

guration," since given to this method, has established an uncertainty as to the method and its author. In his work Dr. Rivière shows that the "blowing off air or carbonic acid-which has been added to his method -is absolutely useless, and that this is the cause of the burn produced by the spark in its contact with the tissues; he adds that the electrode commonly employed is defective, because it is traversed in its whole length by the conducting wire, which provokes short circuit in the operator's hand. The electrode employed by the "father" of the method only receives the current in the active part. With reference to the curette, Dr. Rivière considers that its use is detrimental rather than useful, and that it is preferable to have several séances of alto-frequent scintillation, in order to continue the elimination of the morbid or contaminated cells. As for the modus operandi, Dr. Rivière repeats the formula which he gave in his address to the Congress of Rome: "The voltage and intensity of the sparks and effluves varies with the pathologic equation of the patient; this mode is before all a question of appreciation for the electrotherapeutist and the surgeon.'

### **OBITUARY.**

JOHN HOLDEN WEBB, M.R.C.S., L.R.C.P., of Melbourne.

WE regret to record the death of Mr. John Holden Webb, one of the best-known Melbourne surgeons, on December 10th. We take the following from The Age. Melbourne:—"Upon his arrival in Victoria some thirtysix years ago, Mr. Webb was appointed Resident Surgeon to the Amherst Hospital, and afterwards to a similar position at Creswick, where he remained for several years. Subsequently he settled in Melbourne, and rapidly acquired a reputation and enjoyed an extensive practice as a surgeon. For many years he was one of the surgeons to out-patients at the Mel-bourne Hospital, and was also Acting Lecturer on Surgery at the Melbourne University. He also filled the position of Honorary Librarian to the Medical Society of Victoria. Of late years Mr. Webb devoted himself almost exclusively to the study of cancer. In the treatment of this disease he met with considerable success, and has done much important original work in this connection. He was always a profound student, and one of the best read members of his profession." The name of Webb will always be associated with a cholesterinic theory of cancer, and treatment by sodium oleate injections and internal adminisment by sometime of purified ox gall, which readers of The MEDICAL PRESS AND CIRCULAR will be familiar with. in the writings of Dr. J. A. Shaw-Mackenzie in our columns.

DR. GEORGE DICKSON, OF EDINBURGH.

DR. DICKSON died in Edinburgh on January 18th, in his 71st year. He died in harness, and was doing his usual work up till a week before his death, when symptoms of cerebral hæmorrhage set in, and though he rallied temporarily, a renewed hæmorrhage proved fatal. Dr. Dickson was a well-known and much respected practitioner, his kindliness and courtesy made him esteemed by all who knew him. He was one of the most prominent Scottish Freemasons, and had been connected with the Lodge of St. Mary's Chapel. No. I., for 40 years, and for 5 years, from 1891, he was Right Worshipful Master. At the time of his death he was Librarian and Historian of the Lodge (of which he had edited a history), and he devoted much care to the old minutes, which are in existence from July, 1599. He was a leading member of the Grand Committee of Grand Lodge, and was an honorary member of nearly every Lodge in the district. He was Secretary of the Lodge when the King (then Prince of Wales) was made a member. At the celebration of the targentangue of the Lodge in 1892. Dr tion of the tercentenary of the Lodge in 1899, Dr. Dickson was presented by his brother Masons with his bust in token of their appreciation of his services. Dr. Dickson is survived by a widow and grown-up family. His only son is a medical man, and is the Lecturer on Bacteriology in the University of Edinburgh.

### MEDICAL NEWS IN BRIEF.

The Dublin Branch of the Research Defence Society.

A MEETING to inaugurate a Dublin branch of the Research Defence Society will be held in the theatre of the Royal Dublin Society (by kind permission of the Council) on Wednesday, to-day, January 27th, at 5 p.m. The chair will be taken by Sir John G. Nutting, Bart., D.L. The speakers will be: The Very Rev. the Dean of St. Patrick's; Count Plunkett; Dr. Burne Prog. Pay. Coll Phys. the Right Hon T. W. Horne, Pres. Roy. Coll. Phys.; the Right Hon. T. W. Russell, M.P.; Mr. Stephen Paget, F.R.C.S.Eng., Hon. Secretary of the Society; Rev. Thomas A. Finlay, S.J., F.R.U.I.; and Mr. Alexander Blood, K.C. It is hoped that there will be a very full attendance of members of the medical profession and of their friends.

Action by a Medical Man for Libel.

AT Ipswich, on Friday and Saturday last, the case f "Macleod v. Mullock and Another" was tried. Mr. F. E. Smith, for the plaintiff, said that this was an action for libel. The plaintiff, a medical practian action for libel. The plaintiff, a medical practi-tioner, came, in March, 1907, to settle in Southwold, where the two defendants, Dr. Mullock and Dr. Tripp, were already in practice. In May, 1908, Dr. Mullock, acting on his own behalf and on that of Dr. Tripp, wrote to Dr. Tyson, the honorary secretary of the local division of the British Medical Association, of which the defendants, and not the plaintiff, were members, making certain specific charges of "touting" and other serious breaches of professional etiquette, and asking for the advice of the Divisional Ethical Committee on the matter. Dr. Tyson, having consulted his committee, and having received a telephonic communication from the defendants leaving the matter in his hands, communicated by letter with the plaintiff, specifically indicating the charges which the defendants had made against him, and offering the arbitrament of the British Medical Association should he desire to offer any explanation. The plaintiff, in answer, wrote refuting the various charges made, and expressing a hope that the influence of the Association might result in a retractation and apology by the defendants, though he did not admit its authority to decide such a serious ne did not admit its authority to decide such a serious matter. No apology being forthcoming, these proceedings were commenced. The defendants pleaded that the occasion was a privileged one. It further appeared that Dr. Mullock had, in a letter to the Secretary of the Medical Defence Union, repeated from hearsay other serious charges against the plaintiff for which there was no foundation whatever.

Evidence by the plaintiff and other witnesses in support of the opening having been given, Mr. Hohler submitted that the occasion was privileged, whereupon Mr. F. E. Smith said he was quite satisfied to treat the occasion as privileged and to submit the question

of malice to the jury.

The defendants both gave evidence, and said that they felt justified on the facts before them in going to the British Medical Association for advice, and that they did not expect Dr. Tyson to communicate with the plaintiff. They denied the existence of any malice towards the plaintiff. They still believed the charges made to be true, but had not justified on the advice of their solicitor, there not being sufficient legal proof of the facts alleged.

The jury returned a verdict for the plaintiff with £300 damages.

Death from Hæmophilia.

On January 14th a boy of 16, named Edgar Thomas, of Sheffield, received a slight injury to the inside of his left cheek, inflicted with the broken end of a glass syringe whilst playing with another youth. Bleeding commenced, and continued intermittently, the boy dying six days later.
Mr. J. Kenyon Parker, Deputy-Coroner, held the

inquest at the mortuary.

The mother of deceased, Annie Elizabeth Thomas, said she took the boy several times to the infirmary. Previously, when he had had cuts or scratches, he had bled for hours, and in some instances a day or two. She had two younger sons, both similarly affected.

J. A. Broomfield said he and deceased were playing

with the glass syringe produced, which was broken at the end, before the accident. He was going to squirt when deceased ducked his head and the syringe caught him in the mouth, making it bleed.

Dr. Leonard Daft said the cause of death was exhaustion after hæmorrhage from the wound in the mouth. The boy suffered from a disease called hæmo-Anyone so afflicted might bleed for hours or philia. days from a slight cut. The disease was rare, and ran in families generation after generation. They had had the boy time after time in the infirmary for bleeding and infusions of blood in his knee-joints. It was not necessary, even, that there should be a wound in these cases. Bleeding sometimes started spon-

The Coroner remarked that he did not think Broomfield could be blamed, and the jury returned a verdict of "Accidental death."

#### Barber's Rash.

BEFORE Sir G. Sherston Baker, at Gainsborough County Court, on January 20th, W. R. Randon, brick-

layer, claimed £7 7s. from Horace Francis, hairdresser. Plaintiff's case was that he was shaved twice a week by defendant until October oth. On the latter date he complained of the razor "dragging," and defendant stropped it again before he finished shaving him. On the following day he felt the lower part of his cheek pain him, and nine or ten days later, a rash having appeared, he went to Dr. Passmore, who told him that he was suffering from barber's rash. Defendant did not use fresh towels for every customer.

His Honour: How much does he charge?

Defendant: A penny a time.

Dr. Passmore gave evidence, and, being cross-examined by Mr. Tweed, said that barber's rash was caused by contagion, and was set up by a microbe. The plunging of a razor into hot water before use would not remove the risk of contagion or kill the microbe.

For the defence it was submitted that reasonable care was exercised by defendant, who said he had been in business three years, and had never had a complaint. He used an antiseptic soap manufactured in Sheffield, and always plunged his razors into hot water before use. Cross-examined by Mr. Southron, he said that he shaved about 350 a week, and used from 20 to

30 towels.

His Honour again said that not much could be expected for a penny, but thought that plaintiff had proved his case, and gave a verdict for £4 with costs.

### The Gresham Lectures.

DR. F. M. SANDWITH, Gresham Professor of Physic, will deliver a course of four lectures on February 9th. roth, 11th, and 12th, at Gresham College, Basinghall Street, the subject being "The Results of Recent Research on Certain Diseases," and "The Life Work of Pasteur." The lectures are delivered at 6 o'clook each evening.

### Royal Society of Arts-The Swiney Prize.

A MEETING of the adjudicators of the Swiney Prize was held at the Royal Society of Arts on Wednesday last, when, on the motion of the Lord Chief Justice, seconded by Sir R. Douglas Powell, K.C.V.O. (ex-President of the Royal College of Physicians, London),

work, "Criminal Responsibility."

Dr. Swiney, who died in 1844, bequeathed the sum of £5,000 in Consols to the Society of Arts for the purpose of presenting a prize on every fifth anniversary of his death to the author of the best published work on Jurisprudence. The prize is a cup of the value of on jurisprudence. The prize is a cup of the value of floo, and money to the same amount, and the award is made jointly by the Royal Society of Arts and the Royal College of Physicians. The cup now given is made by Messrs. R. and S. Garrard and Co., after a design specially prepared for the first award by D.

### Medical Sickness and Accident Society.

THE usual monthly meeting of the Executive Committee of this Society was held on the 15th inst., Dr. de Havilland Hall in the chair. In accordance

with their custom for many years past, the Committee devoted the bulk of their time at the first meeting of the year to the examination of special reports on the cases of those members who seem to be unlikely to be ever able to resume professional work. One of the special features of the Society is the practically permanent provision made for those members who appear to be chronically afflicted. When the Society was first started, although this plan was determined upon, and a considerable outlay in respect of it foreseen, yet, as the years have gone by, the number of these chronic cases has increased more quickly than was anticipated, and now, numbering over 40, they require an out-go exceeding £3,000 per annum.

Proposed Medical Library Association.

AT a meeting of those interested in medical libraries. held at Leeds on the 9th inst., it was decided unanimously to form an Association of Medical Libraries, and a provisional committee was appointed to draw up the constitution and rules. Professor Osler up the constitution and rules. Professor Osler (Oxford) was invited to become the first President; and Professor Walker Hall (Bristol) and Mr. Cuthbert E A. Clayton (Librarian, Manchester Medical Society) were asked to undertake the duties of temporary Secretical Control of the Control of t The following are some af the objects of the Association: -(1) Intercourse of those interested in medical library work and the discussion of matters associated with the fostering and care of libraries.

(2) Diffusion of information as to the branches of medical literature specially catered for at different centres, and as to the value of the various books and new periodicals which are issued from time to time.
(3) The promotion of measures whereby a larger number of practitioners in each centre may be induced to utilise the library facilities of each district. (4) The consideration of matters connected with the present rapid increase of periodicals, publication of books, etc. (5) The opening up of better chances of advancement for library assistants. By such means there would be an inducement to parents to put their sons to such an occupation, and the librarians would be able to have better material for training (6) The archange of better material for training. (6) The exchange of duplicate books and periodicals. When the Association is in working order, it is hoped that a certain number of the libraries interested will join together to form a circle for the loan of their research and other literature.

Sleeping Sickness in the Belgian Congo.

SERIOUS study is being devoted by the Belgian Colonial Ministry to the subject of the sleeping sickness. With a view to combating it more effectively, M. Renkin, the Colonial Minister, has just provided for the establishment of six new hospitals for the treatment of patients suffering from the disease. These will be placed under the direction of doctors who have followed a special course at the School of Tropical Medicine at Brussels prior to their departure for the Congo. Credits are spoken of as likely to be demanded for the purpose of reinforcing the medical corps in the Colony.

Society of Apothecaries of London.

The following candidates, having passed the necessary examination, have received the L.S.A. Diploma of the Society, entitling them to practise Medicine, Surgery, and Midwifery:—G. K. Aubrey, J. J. S. Rowe, J. B. Tackaberry, H. B. Waller, and H. V. White.

Royal College of Surgeons in Ireland.

THE Annual College Dinner will take place on Saturday, February 20th, at 8 p.m. precisely. His Excellency the Lord Lieutenant has graciously accepted the invitation of the President and Fellows to be present at the dinner.

THE issue of the well-known guide to the "London Charities," by Herbert Fry, reminds us of the lapse of another year. Those who are interested in the administration of our medical charities will find within the familiar red covers of this little book an interesting mass of information. The price is eighteenpence, and the book is issued in the excellent style of Messrs. Chatto and Windus.

### **NOTICES TO** CORRESPONDENTS.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a Distinctive Signature or Initial, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule. SUBSCRIPTIONS.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January lat and July lat respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

Small announcements of Practices, Assistancies, Vacancies,
Books, &c.:—Seven lines or under (70 words), 4s. 6d. per
insertion; 6d. per line beyond.

DR. W. M.—The only way we know of getting a copy of the Acts in question is to write to Messrs. Wyman and Co., of Fetter Lane, London, E.C. Official copies of Government papers are not always sent to the editors of medical journals, even when the matter dealt with is of obvious medical interest and importunce. A. HENDERSON.—There are many medical missionaries in China, as well as a large number of lay fellow-workers. For the next few years the country is likely to be in an unsettled condition, and, frankly, we should not advise you to go thither on such a mission.

a mission.

#### BRITISH r. CONTINENTAL HEALTH RESORTS.

BRITISH r. CONTINENTAL HEALTH RESORTS.

A correspondent draws attention to the "exaggerated statements which are so common when discussing the merits of a place in regard to invalids, and when there are interested motives sometimes for extolling the characters of such places." He remarks that visitors have this winter been "tempted by the advice of well meaning, but mendacious friends, and equally mendacious and flamboyant advertisements, to try 'Our Own Riviers.' To some extent the misrepresentations referred to are due to the ignorance and self-interests of members of our profession, which should be discouraged."

Certifting Surgeon.—The number of cases of poisoning and of anthrax reported to the Home Office under the Factory and Workshops Act during November, 1998, was 49, consisting of 46 cases of lead noisoning, and one each of mercurial poisoning, arsenic poisoning, and anthrax. In addition 25 cases of lead poisoning (3 of which were fatal) were reported during November among house painters and plumbers During the eleven months ended November, 1908, the total number of cases of posoning and of anthrax was 682, as compared with 592 in 1907. The number of deaths during the same period was 39, as against 38 in 1907. In addition there were 214 cases of lead poisoning (including 36 deaths) among house painters and plumbers during the first eleven months of 1908, as compared with 158 cases (including 34 deaths) during the same period of 1907.

### EXPERIMENTS ON PATIENTS.

### To the Editor of THE MEDICAL PRESS AND CIRCULAR.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—I am afraid your correspondent, Mr. Sers, has never quite mastered the meaning of "analogy"? A hospital can control its operations and treatment. It would, however, be rather difficult (and very risky) for a boarding-house keeper to guarantee that there were not, and never would be, any thieves among the household from cellars to garret! Indeed, it is a question whether, if a case of a thief being there after all occurred, there might not be liability for restitution or compensation! Such are the illogical arguments, the spurious "analogies," and plausible missues of terms which arise, no doubt often from ignorance; but which often mislead on equally ignorant portion of the public.

I am, Sir, yours truly.

I am, Sir, yours truly, GEORGE W. F. ROBBINS.

Tr Quoque (Aberdeen).—The resident medical appointments in the London hospitals, apart from those hospitals with medical schools attached, are quite open; but personal interest with members of the staff is not without value in the selection of a

MAYER, CLIFFORD A. L., M.D., B.S.Lond., M.R.C.S., L.R.C.P. Lond., Senior Resident Medical Officer at the French Hospital, Schere, Gerald Morgan, M.R.C.S., L.R.C.P.Lond., prof. tem., Public Vaccinator for the Kingswear District of the Totnes (Devon) Union.
TROYTER, G. CLARK, M.D.Edin., D.P.H.Aberd., Medical Officer of Health for the Burgh of Paisley.

### Vacancies.

Sussex County Hospital, Brighton.—Stephen Ralli Memorial.—
A Pathologist.—Salary, £350 per annum, and half the fees earned in private practice. Applications to the Secretary of the Hospital.
Bristol General Hospital.—Senior House Surgeon. Salary, £120 per annum, with board, residence, etc. Applications to the Secretary.
Rotherham Hospital and Dispensary.—Senior House Surgeon. Salary, £110 per annum, with rooms, commons, and washing. Applications to the Secretary, H. Kelson, Masonic Buildings, Rotherham.
Northampton General Hospital.—Senior Resident Medical Officer.—Salary, £120 a year, with apartments, board, washing, and attendance. Applications to C. S. Risbee, Secretary-Superintendent.
Durham County Asylum.—Junior Assistant Medical Officer.

Superintendent.

Durham County Asylum.—Junior Assistant Medical Officer.

Salary, £150 per annum, with board, laundry, and attendance. Applications to the Medical Spuerintendent. Durham County Asylum. Winterton, Ferryhill.

Surrey County Lunatic Asylum, Brookwood, near Woking.—

Second Assistant Medical Officer. Salary, £200 per annum, with board, lodging, and laundry. Applications to the Medical Superintendent of the Surrey County Lunatic Asylum, Brookwood, near Woking.

Kensington General Hospital, Earl's Court, S.W.—Assistant Surgeon and Ophthalmic Surgeon to the Hospital. Applications to Louis C. McCausland, Secretary.

Cambridgeshire, etc., Asylum.—Senior Assistant Medical Officer.—

Salary, £150 per annum, with board, lodging, and washing in the Asylum. Applications to T Mugrave Francis. Clerk to the Visitors, 18, Emmanuel Street, Cambridge.

### Marriages.

WILLIAMSON—GRAHAM.—On Jan. 19th, at St. Matthias's, Richmond, John Williamson, M.B., C.M., Rothesay House, Richmond, to Lilian, younger daughter of the late Duncan Graham, of Lydiate, Willaston, near Chester, and of Mrs. Graham, Lansdowne View, Richmond.

### Beaths.

FRANK.—On Jan, 22nd at 3, Elvaston Place. London, the Lady Agnes Frank, wife of Dr. Philip Frank, in her 79th year.

HILL.—On Jan. 22nd. near Andermatt, Switzerland, the result of an accident, Lieut. Herbert E.W. Berkelev Hill, Middlesex Regiment, youngest son of the late Berkeley Hill, M.B., F.R.C.S., and of Mrs. Berkeley Hill, 49, Gloucester Terrace, Hyde Park, aged 21 years. Jones.—On Jan. 23, at 6, Riviern Terrace, Dawlish, Herbert C. W. Jones, M.A., M.B. Cantab., M.R.C.S., L.S.A., late of Acton, eldest son of the late William Jones, formerly H.B.M. Vice-Consul at Havre, and Mrs. Jones, La Quinta, Dawlish. Young.—On Jan. 13th, at Holme Cottage, Paignton. Augustus Warren Young, M.A., T.O.D., youngest son of the late Plowman Young, M.D., of Bury St. Edmunds, in his /2nd. year. R.I.P.

### A few typical letters from Medical Men

about

# ANGIER'S EMULSION

(Petroleum with Hypophosphites).

## "I consider it superior to all other emulsions."

Dear Sirs,—I have used Angier's Emulsion in a number of chest cases, notably in cough following influenza and in the later stages of bronchitis in children, and have never known it to fail. In one case of advanced phthisis it gave a good deal of relief. After trial in a multitude of chest cases, I consider it far superior to all other emulsions.

(Signed) ———L.R.C.P., L.R.C.S.

### "Derived much benefit after an attack of Pneumonia."

Dear Sirs,—Having during the past two winters derived much benefit from taking Angier's Emulsion after an attack of pneumonia, I am, with excellent results, using it largely both in my private practice and also amongst my hospital patients.

(Signed) -----M.R.C.S.

# "Especially valuable in Chronic Bronchitis."

Dear Sirs,—I find Angier's Emulsion especially valuable in chronic bronchitis, and I have no less than seven patients who are at present using it with very marked benefit. In two cases, accompanied with asthma, the effect is very marked indeed. I have observed recently that the stomach can continue to take Angier's Emulsion almost indefinitely without any bad effects, hence I have had patients who were taking other emulsions abandon them in favour of yours. I know of no other preparation from which such excellent permanent results have been obtained. (Signed) L.F.P.S. Glas. & L.M.

## "Excellent results in the treatment of Mucus-Colitis."

Dear Sirs,—I send you this short note to tell you that I have got excellent results in the treatment of mucus-colitis from the administration of Angier's Emulsion. It is in my experience by far the most useful preparation in such cases. Also in Bronchitis, specially of old people who cannot digest cod-liver oil, I find your Emulsion very valuable. I have not got as good results from any of the imitations, and I invariably prescribe Angier's.

(Signed) ———M.B., etc.

## "I prescribe it to more than half my patients."

Dear Sirs,—In all cases of chronic cough, and in all wasting diseases of adults and children, pulmonary and gastro-intestinal, I find no better tonic than Angier's Emulsion. I prescribe it to more than half my patients. You may make use of this testimonial minus my name.

(Signed) ———L.R.C.P., L.R.C.S., &c.

### "Decided benefit in troublesome Bronchial Catarrh."

Dr. — begs to thank the Angier Chemical Co., Ltd., for their Angier's Emulsion, which he has taken with such decided benefit in troublesome bronchial catarrh that he is pleased to add his testimony as to its great value as a tonic and to endorse every word of their prospectus as to its effects and advantages over other emulsions of fatty medicines, generally so nauseating, but in this case positively pleasant to take.

(Signed) — L.R.C.P., M.R.C.S.

## "It is as well adapted to children as to adults."

Dear Sirs,—I have pleasure in stating that I have used Angier's Emulsion now for a period of over three years in my practice with great success, both in acute and chronic stages of pulmonary diseases, also in gastro-intestinal disorders, especially of a catarrhal, ulcerative, and tubercular nature. It is as well adapted to children as to adults. I use no other emulsion.

(Signed) ----L.R.C.P., L.R.C.S.

# Catarrhal Tracheitis Patient over seventy.

Dear Sirs,—I have tried Angier's Emulsion on my wife, who was suffering from an acute attack of catarrhal tracheitis and was over 70 years of age. I gave it in maximum dose an hour after breakfast time—once a day only. In ten days the awful tickling cough, which no drug or treatment ever restrained, almost entirely left her and within seven days more was gone. I therefore, unsolicited by you, feel I ought to state the case for the good of others.

(Signed) ——M.D. Edin.

### Free Samples to the Medical Profession.

# STYPTOL

An opium derivative which has proved to be a more reliable and more efficient drug in the various forms of uterine hæmorrhage than hydrastis, hamamelis, ergot, &c. It has proved especially effective in cases of severe

### Menorrhagia and Dysmenorrhœa

It is also beneficial in metrorrhagia, threatened abortion, after operative measures, in climacteric hæmorrhage, and in new growths. It relieves pain and prevents imflammation, and is free from any injurious action on the heart or the digestive apparatus. As it never causes contractions, it can be administered with safety during pregnancy.

Doss : 2-3 tablets (3 grain each) ter die.

JU-YIS

### The "Lancet" on Cocoa.

Of the beverages in common use (Tea, Coffee & Cocoa), Cocoa is the best, because—

- 1. It is not a mere stimulant; it is also a true food.
- 2. Its stimulant value is similar to that of beef tea, and its nutritive value bears comparison with that of milk.

Of test cocoas bought in the open market, Van Houten's proved to be the best; because—

- 1. It is the most finely sub-divided, leaving no sediment in the cup.
- 2. It is the most soluble and perfectly miscible, consequently the most economical in use.
- 3. It is the most readily digested in the gastric juices.
- 4. It contains the maximum proportion of the proximate principles of food.

These facts, elicited by unbiassed scientific investigation (vide "Lancet," Jan. 7th and Feb. 4th, 1905) place Van Houten's Cocoa in the front rank of modern dietetic preparations.

It is quickly absorbed in the stomach, leaving no undigested irritant residue, and is therefore pre-eminently suitable for invalids.

## VAN HOUTEN'S COCOA.

### 

A Pancreatised Food that can be made in a minute, the addition of boiling water only being necessary.

BY the use of the "Allenburys" Diet all trouble of peptonising milk and farinaceous foods is overcome. In the sick room it is invaluable, as the food is easily digested and assimilated, and only the exact quantity required need be prepared at a time.

The "Allenburys" Diet is made from pure full cream milk and whole wheat, both ingredients being partially

pre-digested during manufacture. It can be taken by those who cannot digest cow's milk, and provides a light and very nourishing diet for Invalids, Dyspeptics, and the Aged.

For travellers by sea or land this complete food will be found exceedingly valuable.

Sample, with full particulars, sent free on request.

### Notes and Comments.

THE paucity of medical men in the Medical Men House of Commons is a stock subject of lamentation amongst those Parliament. that hope to better the conditions of our profession. Of the few niedical men who write "M.P." after their names, the majority sit in Parliament as political and party Parliament. representatives. Indeed, it is the exception rather than the rule for them to interfere in the discussion of matters of medical interest. One of our best friends in the House of Commons is probably Sir Batty Tuke, who has always stood up manfully in the defence of professional interests. Amongst others, thanks are due to Sir William J. Collins, M.D., who has done good service during the few years he has been in Parliament. One successful effort of the kind is noted at length in the leading columns of our present issue. It relates to the extraordinary lapse from ordinary good taste and patriotism involved in the appointment several years ago by Sir Claude Macdonald of a German medical man to the Embassy at Tokio, the capital of Japan. Sir William Collins brought the matter to the attention of Sir Edward Grey in a series of pointed parliamentary questions. Although the matter was shelved and evaded at the time with the skilful circumlocution apparently inseparable from Foreign Office methods, we are glad to say that the justice of Sir William's contention has been tacitly conceded by the tardy substitution of an Embassy medical officer holding a British qualification.

Why not
More Medical men in Parliament are not
far to seek. The demands upon the
"M.P.'s"?

time of the Members are more and
more exacting, and, at the best, are

well-nigh impossible to anyone conducting a large practice. Some few exceptional men are able to do their duty in the House and not neglect their hospital and private consultant or specialist practice; but these are necessarily few and far between. Then there is the matter of the cost entailed in the membership, both as regards elections, the nursing of constituencies, and the actual expenses incident to residence and other matters pertaining to the parliamentary sessions. It seems likely that these various obstacles are so great as to render anything like adequate representation of medical men in the Commons out of the question, unless and until the matter is treated as a collective duty, and the expenses of a certain number of medical men be paid, as in the case of the Irish and the Labour parties. The medical profession, in the aggregate, can wield an enormous political power, and it is not improbable that, were the initial money difficulty overcome, they would be able to command the polls in a sufficient number of constituencies to satisfy all the needs of the situation. So mote it be!

Army Medical Promotion. THERE are already to be heard grumbles about the system of promotion adopted in the Royal Army Medical Corps some eighteen months ago. Under the reforming hand of

Mr. Haldane-whom we are proud to recognise as a brother-scientist, in spite of his legal attainments -a move was made in the direction of abolishing promotion by seniority in favour of promotion by merit. To this end, a board consisting of six majorgenerals on home stations was appointed to advise on the advancement of officers. The plan was welcomed generally by the corps, both as substituting a logical system for an automatic one, and also as placing members under the control of their own professional superiors. In human affairs, alas! there is always some defect, and such a system always exposes administrators to the charge of favouritism. Indeed, the old method of seniority promotion was really a reaction against the jobbery that previously went on. And so the action of the board in selecting certain officers and passing over others is being criticised, though, from what we gather, there is really no serious charge brought against it. The corps has suffered so much in the past from dissensions inside and outside the ranks, and the way has been so favourably prepared by Lord Middleton and Mr. Haldane for peaceful progress, that we trust satisfaction will reign for many years to come.

Coleridge v. Kidd. THE amicable relations which exist between the various anti-vivisection societies were exhibited again by a summons heard in the Chancery Division last week before Mr. Justice

Joyce. The point at issue was which society, Mr. Coleridge's or Miss Kidd's, was entitled to a legacy of £200 left by a benevolent lady, Miss Caroline Goldsmid, "to the treasurer for the time being of the Anti-Vivisection Society, Bristol Branch, for the purposes of the said Society." The Bristol branches of the two societies each put in a claim for the legacy. As Miss Goldsmid was a life member of the British Union for the Abolition of Vivisection, and had never subscribed to the National Anti-vivisection Society, one would think it plain that the Bristol branch of the former concern was intended. However, an anti-vivisectionist is nothing if not militant, and as the dispute continued, it became necessary to obtain a legal interpretation of the will by means of an originating summons. Mr. Justice Joyce said that there was no doubt that the

British Union was intended, and awarded the legacy to it, or perhaps we should rather say, what was left of the legacy after the legal gentlemen concerned have all had their share. An interesting observation fell from his lordship in the course of the announcement of his decision—that the Bristol branch of the National Anti-vivisection Society "appeared to be only for the purpose of collecting funds and remitting them to the head office in London"!

The Mother State.

The Woman's Labour League, in session at Portsmouth, was occupied with a number of social questions of grave moment, but as the whole tendency of all these debates is to

centre on Socialism, the amount of immediate practical utility would seem to be small. All of those who have thought of the influence which the labour of married women has on the home must have been struck both with its immense social and hygienic importance, and with the difficulty of tackling it. One good lady gaily suggested that all married women should be forbidden by law from working for their living—a proposal which could only come from a person wholly unacquainted with the necessities of the situation. Another lady, Miss MacArthur, declared that what is necessary is, that the State should make provision for mothers four months before child-birth and a year afterwards. That, perhaps, is nearer the mark, but we fail to see how it could be carried into practical effect; the dangers of it, however, are obvious, for the next step is clearly to make the State responsible for the children altogether-an arrangement which would, no doubt, tend to increase the population, but without taking count of the sort of citizen which would result. The difficulty is to preserve the home, protect the mother, and preserve the independence of the individual. A practical solution is still awaited.

A GOOD stand is being made at Brentford by the medical men of the 3½d. a Visit. district, who have combined together and refused to accept less than 65. per head per annum from members of

the friendly societies. In South Manchester and the neighbourhood a similar stand was recently successfully maintained. It is asserted that the present rate of 4s. in Brentford averages out at 3½d. a visit! We only wonder that the profession has taken no concerted action before. The friendly societies must have the interests of their own members very little at heart, or they must be extraordinarily impervious to the facts of life, if they imagine that careful modern medical treatment can be meted out at such rates. The worst form of economy for a working man who depends on his own exertions is economy in medical treatment when he is ill, and the sick funds of the societies are likely to be largely depleted through the prolongation of members' absence from work if they are not adequately and fully treated for their complaints.

### LEADING ARTICLES.

THE FOREIGN OFFICE AND AN OFFICIAL MEDICAL APPOINTMENT.

In the year 1905 the attention of the medical profession of the United Kingdom was drawn to a curious state of affairs affecting their dignity and standing in no less important a country than that of Japan: We are glad to say that the particular rock of offence in question has

been at length removed, thanks mainly to the exertions of Sir William J. Collins, one of the few representatives of the medical profession in the House of Commons. Although the incident is now happily concluded, the matter, nevertheless, has so much inner significance that the story and its moral may with advantage be brought to the recollection of our readers. It appears that there are some seven British embassies and consulates to which medical officers are appointed; the posts are salaried and non-pensionable, but the holders have the right to carry on private practice. One of these posts at Tokio, the capital of Japan, was for a long time held by a German medical man, and when the post became vacant it was conferred by Sir Claude Macdonald, the Ambassador at Tokio, upon another German. The legality of such an appointment is open to serious question, inasmuch as the Embassy, by a legal fiction, stands upon British soil, and is open to foreign medical practitioners only upon clearly defined conditions. As to the moral effect of such a step, there can be no hesitation in describing it as disastrous. The Japanese, a shrewd people, seeing the Embassy going to Germany for its medical advisers, immediately jump to the conclusion that English people have greater faith in German medicine. Whether this motive be responsible or not, it is a fact that of recent years Japanese students have to a great extent deserted our own medical schools for those of Germany. Who can wonder at such a preference when the English Ambassador, who is placed in Japan to foster and protect British interests, sets so poor an example of faith in our medical men? Sir Claude Macdonald, however, may rest assured that in the field of actual practice, as apart from arm-chair pedantry, the British practitioner stands unrivalled as a sound practitioner abreast of the principles of modern scientific methods. When Sir Claude Macdonald's attention was drawn to the undesirability of appointing a foreigner to so important a post, he responded in a way that appears to be derogatory of the traditions of dignity and of patriotism that should distinguish a British Ambassador to a great nation like Japan. The matter was taken up in the medical journals, and a remonstrance addressed to His Excellency by the British Medica! Association. We had always imagined that a British Ambassador was responsible solely to the Foreign Office, but Sir Claude took the extraordinary step of corresponding with the Association in defence of his action. That communication, in our opinion, stands self-condemned, inasmuch as it descends to the extremely undignified level of attempting to belittle a gentleman, Mr. S. G. Kirkby-Gomes, a Fellow of the Royal College of Surgeons of Edinburgh, who was at the time resident in Tokio as professor of surgery at the College of Medicine, and who, in our opinion very properly, had drawn the attention of the Association to the facts of the Embassy appointment. The Ambassador further stated to that body, in so many words, that he had not appointed the German until every means of obtaining an English candidate had been exhausted. To that assertion Mr. Kirkby-Gomes pertinently inquired whether the vacancy had been advertised in one of the home medical journals—a question that we believe still remains unanswered. If Sir Claude

Macdonald's original appointment was bad, his defence appears to be many times worse, inasmuch as it reveals an arrogance and a failure to grasp the essentials of a position that are simply startling to find in connection with a British Ambassador. His attitude throughout the affair has been practically censured by Sir Edward Grey and the Foreign Office by the recent appointment to the Tokio Embassy of a practitioner holding a British qualification. Sir Claude Macdonald, whose services were transferred from China to Tokio after the Boxer rebellion, has neither added to his laurels nor increased the prestige of his office and of British medical science by his handling of the medical officership of the Embassy in Tokio. The Diplomatic Service is, for the most part, a mystery to the man in the street, but if it fail in so elementary and obvious an international duty as the defence of that medical science of which we as a nation are so justly proud, then the sooner the traditions of the Foreign Office are rehabilitated the better for the Empire. Meanwhile, the thanks of the profession are due to Mr. S. G. Kirkby-Gomes and Sir William J. Collins for their spirited and disinterested action in the defence of professional rights.

### RADIUM IN SURGERY.

THE newspaper reading world has been startled lately by the report of a lecture by Sir Frederick Treves on the use of radium in surgery, and still more so by the announcement that Sir Ernest Cassel has allotted a large sum to endow in perpetuity an institute for the scientific study of radium and its application to clinical cases. Since Sir Frederick Treves was "unmuzzled," by reason of the fact that he retired from practice, he has been acting somewhat the part of a medical fat-50y whose delight is to make the flesh creep, and his outspokenness and assurance, which were so well known in professional circles for the last two or three decades, have enjoyed a wider vogue since his successful operation on the King. Now, we have nothing more to say of his lecture on radium than that we hope the outlook of that element in therapeutics is all that is there painted. If radium will heal epitheliomata, rodent ulcers, nævi, and other superficial growths and formations with the case which Sir Frederick describes, no one would be more delighted than ourselves. At the moment we can only say that, our own experience not having been so satisfactory as Sir Frederick's, we are not in a position to say more than we shall be glad to know in what direction we have erred, and trust the mistakes of the past may be rectified in the future. There are three sets of emanations from radium, says Sir Frederick, namely, alpha rays, of low velocity and penetrating power, beta rays, of great velocity and penetrating power, and gamma rays, of enormous velocity and penetrating power, the latter two varieties being inseparable. fault which has prevented other observers from obtaining results as good as those seen by Sir Frederick Treves is, according to that authority, that they have not applied the radium in the correct way, which consists in using a little of the element spread over a large surface. Employed in this

manner, radium acts much more powerfully than when a piece of it is placed in a tube, and is capable of destroying epitheliomata and other lesions which X-rays have failed to effect. Distance and duration are important factors in the treatment, and these can only be learned by time, trouble, and experience, and they vary according to the result the surgeon wishes to secure. But external treatment is by no means the only kind which Sir Frederick Treves conceives to be within the therapeutic purview of radium. He discussed the inhalation of radioactive substances into the lungs, and cited an instance in which an experimenter had injected a radio-active solution into a mouse suffering from artificial cancer. The result of the latter research was the rapid disappearance of the growth. Well, far be it from us either to doubt the facts or to chill the ardour of those working on this wonderful and little-understood substance. We trust such studies may be brought to the happiest fruition in the treatment of disease and the increase of longevity. But we cannot help thinking it a little odd that Sir Frederick Treves, who was during his active career as a practising surgeon such an ardent advocate of operation as opposed to medical measures, should be the mouthpiece of the new treatment. That in itself is no reflection, but only one of the little ironies of life. And, further, we must deprecate, though we feel somewhat churlish in doing so, the flourish of trumpets over the endowment and foundation of the new institute. Perhaps, like the Pharisees of old, we are inclined to take the jaundiced view-can any good thing come out of Nazareth? On the other hand, looking back on an endless vista of alleged therapeutic triumphs, heralded into the world with every circumstance of promise, and seeing at the end nothing but disappointment, we feel we can safely say that the drums, the trumpets, and the laurel-leaves, come better after the race is won. Let us hope that radium may be all that is announced, but let us wait before acclaiming it till we have complete demonstration. And, further, let us hope that there may be none of the tragedies among workers in radium which have so cruelly overtaken the earlier X-ray experimenters.

### CURRENT TOPICS.

The Research Defence Association.

Few societies can boast of the rapid progress shown by the Research Defence Association during the twelve months since its foundation. It is just a year ago that seven men met round Mr. Stephen Paget's dining-table-a table at which many great men have foregathered in times past-and decided to found the Association. To-day more than 2,200 members have been enrolled, and the Dublin meeting last week showed that the movement is still growing rapidly. It was time that the resistance to the anti-vivisectionists should be organised, and brought to bear directly on public opinion. By their noise, rather than by any inherent force in their reasoning, the anti-vivisectionist party has made itself felt, for, whenever anyone shouts loud enough, the English public thinks there must be something worth hearing. In Dublin this winter it is said that the Hospital

Sunday Fund suffered severely by reason of an attack from some untruthful statements made by anti-vivisectionists. It is very gratifying, therefore, to find the hearty response of the best elements of the public to the appeal of Mr. Stephen Paget and those associated with him in the Research Defence Association. Professional men of all kinds, business men, clergy, public men, with large numbers of ladies, were present at the meeting in Dublin. It is needless to say that the Association has the hearty and unanimous support of the medical profession. Sir Henry Swanzy, who must be regarded as directly responsible for the foundation of the Dublin branch, is to be heartily congratulated on the results of his labours.

### Live Burial.

It is curious how, from time to time, the fear of being buried alive crops up in the public mind. A few years ago, on the death of a well-known antivivisectionist lady, it was declared that she had given directions that her heart should be transfixed in order to ensure that death had occurred. Last week, in an advertisement in an Irish paper regarding the estate of a gentleman recently deceased, there was notice of the bequest of two guineas to a Dublin medical man for the performance of a similar test of death. While it would be futile to deny that under certain circumstances, as, for instance, during a cholera epidemic, persons may have been buried alive, it may be stated without hesitation that under ordinary conditions such an event never occurs. Those who dread live burial rely to a great extent on the distorted condition in which bodies buried for some time may be found. But they entirely reject the known fact that putrefaction may produce the most curious distortions, and that violent effects on the coffin, even to the bursting of a sealed leaden casket, may be brought about by the gases produced by putrefaction.

Nursery Schools.

Now that the folly of sending children under five years of age to school is becoming recognised, not only by the Board of Education, but by a good many local authorities as well, the serious question arises as to what is to be done for children who have hitherto attended the infant classes at schools. One of the proposals is that so-called "nursery echools" should be established, and that these should be conducted somewhat on the lines of the crêche, that is, as institutions to which parents may send their children with the frank intention of getting rid of them for the day. There is a good deal to be said for such institutions, but the most important point about them is that they should not be regarded as, or conducted on, the principle of the school. That education, as ordinarily understood in the school curriculum, is not only unnecessary for, but positively harmful to, children under five, is accepted by all who have studied children scientifically, and it is recognised, moreover, that any teaching between the ages of five and seven must be of the simplest description, and conducted on quite different principles to those usually adopted. In our educational system, however, there is no room for any nursery schools without a complete overhauling of all the machinery, and it is doubt-

ful if they can be grafted on anything which at present exists, without there being confusion in people's minds as to their object. Such nursery schools, in fact, should be not schools at all, but playrooms, and it is far from certain that the authorities at Whitehall would give grants to institutions, by whatever name called, which did not even profess to instruct. Whilst unreservedly condemning any attempt to begin a child's education so early, we tear nursery schools would still present another of the great objections to the present infant departments, namely, that they would continue to act as the hotbeds of infection for measles and whooping-cough. The subject seems to us part of a far wider one. The natural and proper place for children of tender years is the home, and their proper guardian and teacher is the mother. No institution and no teacher should be needed to supply the place of either, and we cannot but believe that the whole position is a strong argument against married women during active sexual life going out to work, or being looked upon as wage-earners at all.

The Ethics of Dispensing.

In a recent number of The Pharmaceutical Journal there is the report of an interesting paper on the relations that should exist between prescriber and dispenser in cases where difficulties arise. In some cases—less numerous than the article in question seems to imply-a dispenser is presented with a prescription which, either by reason of incompatibility or of massive dose, seems to him to present elements of danger. What is his duty under such circumstances? The obvious answer is, that he should communicate with the prescriber. It seems, however, that some dispensers are chary of doing this, in view of the possible snub they may receive. Mr. McEwan relates the case of a dispenser to whom was presented a prescription ordering 20-minim doses of dilute hydrocyanic acid. He communicated with the prescriber, who requested him to dispense the prescription as it stood. He did so, but the prescriber wisely called on the patient at once and altered the dose. It seems to be impossible to lay down any absolute rule on the point. Every case must be decided on its merits. With a sincere desire on the part of the pharmacist to protect the public, and at the same time to maintain the confidence of the patient in his physician, few real difficulties will arise. While a dispenser has in most cases done his duty in drawing the attention of the prescriber to any possible danger, yet there is no doubt that, if still unsatisfied, he has the right to refuse to dispense. In his own interests he is not likely to enforce this right at all frequently, but a pharmacist is no more bound to dispense every prescription presented to him than a medical man to advise every patient who demands his services.

"Running Amuck."

The terrible outburst of madness known in the East, especially in the Malay, as running "amok," has been converted into the easier phrase, "running amuck," by British sailors. As we all know, the unhappy victim of the frenzy attempts to kill everyone he meets, and the condition is essentially one

of acute homicidal mania. As a form of insanity, it affects individuals, and, happily, does not permit of the co-operation or concerted organisation of two or more persons. That fact at once upsets the theory that the two desperadoes who were chased for miles the other day in the outlying suburbs of London were victims of this particular form of madness. Had there been only one ruffian firing his revolver indiscriminately at everyone within range during several miles of a wild race on motor, tram and other vehicles, he would probably have been a case of a man gone "amok." But there were two assassins, who had first planned a deliberate robbery, and left their home laden with cartridges for their criminal fight. Theirs was the organisation of intellectual sanity, whatever may be said of the moral failure that could have rendered possible the development of such collective ferocity.

### PERSONAL.

THE KING has appointed Mr. George Anderson Berry, M.B., C.M., F.R.C.S.Ed., to be Honorary Surgeon Oculist to His Majesty in Scotland in the place of the late Dr. Argyll Robertson.

HIS MAJESTY THE KING has graciously granted permission to Dr. George Ogilvie to accept and wear the Insignia of Knight of the Royal Order of Isabel la Católica, conferred on him by the King of Spain.

PRINCESS CHRISTIAN has given her patronage to the matinite which is to take place at the Queen's Theatre, Shaftesbury Avenue, on Thursday, February 18th, in aid of the funds of the Royal Ear Hospital, Dean Street.

PRINCESS CHRISTIAN was present at a meeting of the League of Mercy held at the St. James's Theatre on January 28th. The speakers included Sir W. J. Collins, M.P., M.D., Captain H. M. Jessel, Mr. H. B. Irving, and the Mayor of St. Pancras.

Dr. Albert T. Ozzard, of British Guiana, has been elected to the West India Committee.

Mr. RUSSELL HOWARD, M.S., F.R.C.S., has been appointed surgeon to the Poplar Hospital.

SIR WILLIAM GOWERS, F.R.S., will lecture at University College Hospital this afternoon on "Unilateral Optic Neuritis from Cerebral Tumour."

THE British Association is to meet this year at Winnipeg from August 25th to September 1st. Profesor Sir J. J. Thomson, F.R.S., is the President-Elect.

Dr. RAMBAUT. Superintendent of the County Asylum at Bicton Heath, was last week the recipient of a hand-some present, subscribed for by members of the staff, on the occasion of his marriage.

MR. HERBERT C. MOONEY, M.B.R.U.I., F.R.C.S., Assistant Surgeon to the Royal Victoria Eye and Ear Hospital, has been appointed Assistant Surgeon to the Ophthalmic Department of St. Vincent's Hospital, Dublin.

Dr. Sidney Martin, F.R.S., is giving the Lettsonian Lectures of the Medical Society this month on "Functional Disorders of the Stomach and Intestines, their Diagnosis from Organic Disease and their Treatment."

LIEUT.-COLONEL J. W. T. GILBERT, V.D., Royal Army Medical Corps (Territorial), has received His Majesty's permission to accept the silver medal of the Order of Orange-Nassau, confered upon him by the Queen of the Netherlands.

THE Nottingham Medico-Chirurgical Society have presented Alderman Dr. F. R. Mutch, who recently resigned the Chairmanship of the Health Committee of the Corporation, with an illuminated address in acknowledgment of his services to the city.

By invitation of the Council of the Royal Society of Arts an illustrated lecture was given by Dr. James Cantlie on "The Part Played by Vermin in the Spread of Disease" on Wednesday, January 27th, at the Society's rooms. The chair was taken by Sir Malcolm Morris, K.C.V.O.

SIR JOHN TWEEDY, F.R.C.S., is to preside at a meeting to be held on Tuesday, February 9th, in the library of the Royal College of Physicians, in support of the British Medical Benevolent Fund. The Lord Mayor, the Bishop of Oxford, and Sir Douglas Powell, K.C.V.O., will be amongst the speakers.

A COURSE of eight lectures on National Eugenics, in connection with the Galton Laboratory, will be given at University College, London, on Tuesdays at five o'clock, beginning on February 23rd. The first lecture will be given by Professor Karl Pearson on "The Purport of the Science of Eugenics."

LORD ROBERT CECIL will take the chair at the dinner of the London School of Clinical Medicine, to be held at the Savoy Hotel, on February 19th. The guests will include Sir Thomas Smith, Bart., Sir William Church, Sir William Collins, M.P., Sir Malcolm Morris, K.C.V.O., Sir Thomas Barlow, and Sir R. Douglas Powell, K.C.V.O.

THE annual meeting of the After Care Association for poor persons discharged recovered from asylums for the insane will be held at 26 Devonshire Place, W., this afternoon, when the chair will be taken by Dr. G. H. Savage. A paper will be read by Dr. Robert Jones on "The Urgent Necessity of Helping Mental Convalescents."

THE Third Annual Dinner of past and present students of the Royal London Ophthalmic Hospital will be held at the Trocadero Restaurant on February 10th, under the presidency of Sir Anderson Critchett, Bart., C.V.O. The hon. secretaries are Mr. Arnold Lawson, 12 Harley Street, W., and Mr. J. Herbert Parsons, 27 Wimpole Street, W.

Four lectures will be delivered on Tuesday, February 9th; Wednesday, February 10th; Thursday, February 11th; and Friday, February 12th, 1909, at Gresham College, Basinghall Street, E.C., by F. M. Sandwith, M.D., Gresham Professor of Physic. Lecture I. will deal with "The Results of Recent Research on Certain Diseases"; Lecture II. with "Diphtheria"; and Lectures III. and IV. with "The Life-work of Pasteur."

The annual general meeting of supporters of the Queen Alexandra Sanatorium, Davos, was held at the Grand Hotel and Belvedere, Davos-Platz, on January 20th. Dr. W. R. Huggard, Chairman of the Board of Management, who presided, announced that Lord Balfour of Burleigh, President of the Institution, had recently received from Lord Strathcona a donation of £2,000. Dr. Huggard said that the King had given special permission for the Royal Arms to be placed on the building in stone.

### A CLINICAL LECTURE

### SIMULTANEOUS EXISTENCE OF CONGENITAL AND ACQUIRED DISEASE OF THE HEART.

By PROF. A. DIETRICH. M.D.

Prosector at the Krankenhaus, Westend-Charlottenburg, Berlin,

[SPECIALLY REPORTED FOR THIS JOURNAL.]

I wish to describe to you in few words a heart that is not specially remarkable itself, except that it contains in a remarkable manner a combination of unimportant congenital peculiarities and acquired changes that, together, make up an exceedingly grave condition. For this reason the case is of interest to the practitioner regarding the clinical features and a comparison of them with the anatomical condition.

The heart is from a man, æt. 42, who, on account of a "weak chest," was not taken for a solider, but who was ignorant of any heart mischief. As a child he had measles and scarlatina, and twenty years ago he had a long attack of sciatica. He married and had children, but ten years ago he had both syphilis and gonorrhea. In the beginning of 1907, some nerve trouble led him to a nerve specialist, who diagnosed disease of the heart, of which the patient knew nothing. Since May of the present year he has had a cough, palpitation, and sleeplessness. These troubles increased to such a degree that he could scarcely get about, and led him to seek admission into hospital.

On examination of the patient, an elastic fulness of the superficial veins, especially those of the thorax and of the eyelids, was a striking feature, but there was no œdema. The dulness over the heart reached upwards to the fourth rib on the right to the middle of the sternum, and on the left to the mammillary line. Breathing systolic and diastolic murmurs were heard over all the cardiac orifices, the impulse at the apex was heaving, pulsation was visible in the epigastrium, and a capillary pulse was distinctly to be felt. The pulse at the wrist was quick and high, regular, and 92. Nothing special was noticeable in the other organs, there were a few bronchitic rales in the lungs, a trace of albumin in the urine, numerous leucocytes, a few red blood corpuscles, hyaline and granular cylinders.

The condition of the patient got worse, at first a pronounced systolic venous pulse was visible in the neck, the radial pulse was irregular, the condition of the heart was otherwise the same. Cheyne-Stokes respiration was present for a time, dulness in the dependent parts of the chest of the right side, weakened respiration, and ædema of

the legs.

The patient then, against the doctors' advice, left the hospital, but returned in eighteen days with still further advanced mischief. Cutaneous swelling over the abdominal walls and hands was, added to the œdema, and the breathing was very bad. The margin of the heart could now be percussed over the right edge of the sternum, and to the left two finger-breadths outside the nipple line. The murmurs showed no change, the pulse was regular, quick, and high. Blood pressure, 175 mm. Ascites was now present, no sediment or albumin in the urine. The odema receded under treatment, but in a few days the temperature, that had hitherto almost always been normal, rose to 39.3°C., at the same time a rasping sound was added to the systolic and diastolic murmurs that gave rise to a suspicion of pericarditis. The cardiac dulness showed no change, dulness was present in the lower parts of both lungs.

After rapid subsidence of the fever, the objective condition remained the same, but it is specially to be noticed that the venous pulsation before mentioned was persistently present. The ædema slowly increased, and also the dulness over the lungs. The symptoms became threatening a week before the fatal termination, in the form of attacks of angina pectoris, which came on with increasing frequency till death took place on March 17th, 1908.

The diagnosis, based on the clinical history thus shortly related, was one of insufficiency and stenosis of the aortic valves, further insufficiency of the tricuspid valves, changes in the cardiac musculature (myocarditis), and, with some probability, pericarditis. The cause of the disease of the heart, however, was not clear, as there had been no acute symptoms previously, and the course was so extremely rapid from the onset of the first symptoms. From all this the physicians in the case expected to see some serious changes in the heart.

The post-mortem examination showed the whole of the thoracic aperture to be taken up with the pericardium, which was filled with a large quantity of clear fluid, but the serous coating was smooth and shining. The heart was twice as large as the fist of the dead man, distended distinctly more in breadth than in height, the breadth at the base was 16 cm., the length in front 12 cm. Both halves of the heart were filled copiously with fluid blood, and but little clot. On pouring in water the aortic valves were seen

not to effect a proper closure.

Inspection of the valves did not reveal any change in the pulmonary or mitral valves; they were well formed, thin, and their edges were smooth; of the aortic valves, however, only the posterior one was delicate and translucent, free and readily movable, the two anterior ones were adherent, and from this spot to a third of the margin of a whitish colour, of an irregular hard character, shortened longitudinally, thickened at the edge, but without any deposit or nodules. The septum formed by the adherent parts was still more contracted than the free margin, so that the two valve sinuses were only separated by a low bar. These changes in the aortic valves, perhaps more marked in the description than as they appeared in reality to the eye, passed over in the bottom of the sinuses into a flat nodular, whitish, callus-like thickening of the inner wall of the aorta, which extended from the valves about 2 cm. up the aorta, bounded laterally by the

two coronary arteries, but so that the right remained quite free and as a round opening, whilst the left was surrounded by the nodular surface and contracted to a narrow lumen. change of the wall of the aorta, to finish with it was to the eye principally a thickening of the irtima without regressive metamorphoses, in the upper part of the ascending aorta a small flattish prominence was still to be seen, also just above the posterior valve, but the wall of all the other large vessels was quite smooth.

The slight changes of the aorta which microscopically showed the appearances of an ordinary arterio-sclerosis, without signs of any syphilitic causation, first allowed their importance to be estimated by carefully following the coronary arteries of the heart. The usual course of these is that the left coronary artery divides into an anterior vertical branch along the anterior longitudinal fissure, and a horizontal one, which reaches the back of the left ventricle and spreads there into branches, principally in the left lateral angle; the right coronary artery with its main stem runs in the horizontal furrow to the right of the right ventricle, gives off a branch along the right angle of the heart, and runs into the posterior vertical furrow, thus on the borders between the right and left ventricle towards the apex of the heart, but still supplies part of the posterior wall of the left ventricle.

In the case under discussion, the development of the right coronary was but imperfect, from its commencement it was much finer, and did not run over the posterior wall of the ventricle, and the vessel running over the right edge of the heart was the last great offshoot, which could not be followed in the non-injected preparation. On the other hand, the region supplied by the left coronaria was extended. It supplied not only the anterior wall of the left ventricle, and the left angle of the heart, but ran under the large coronary vein, as a large vessel, to the posterior vertical furrow, and in this to the apex. It has, therefore, taken on the duty of the smaller right artery, and with it the whole supply of the cardiac septum on the anterior and posterior sides. The wall of the whole of this vessel is delicate and smooth, but its opening from the aorta is narrowed as we see. With the ill-developed right, this would have been without any consequences as the larger artery by anastomoses of its finer branches, without the specially large left coronary artery on which three-fourths of the heart is dependent, the blood supply of the muscles of the heart must be seriously interfered with.

At the same time, the slight change in the muscles is striking. No necroses are to be seen, no callus from chronic coronary sclerosis, no microscopic degenerative changes whatever are to be seen. The muscles are everywhere red and of firm consistence; the walls of both ventricles are hypertrophied.

But before going further with our consideration of this condition, we must cast a glance on the tricuspid valves. In doing so, the unusual size of the pars membranacea of the septum of the ventricle at once strikes us. Usually scarcely recognisable viewed from the right, covered by the apex of the middle tricuspid, partly situate on it, it forms here a membranous surface 1.5 to 2 cm. in diameter. Above all, the apex of the tricuspid usually inserted into the septum is missing; the strands of tendon springing from

the septum deviate from each other to the posterior valve and to the median valve, present only as regards its posterior half. Between them is a space of nearly a finger-breadth, circular in shape, when the apices of the tricuspid which are firmly attached to the margin are put on the stretch. Here also there are no signs of any old endocarditis; it appears certain that a faulty development was associated with the unusually large membranous septum.

We now have all the peculiarities of the condition, and it is an easy matter to build up the whole of the features of the illness. All the remaining organs showed only the consequences of grave cardiac insufficiency, which I shall not enumerate in detail. The death is due simply to the changes, and to the cardiac paralysis resulting from them. We have two congenital anomalies of the heart, the deficiency in the tricuspid, and the unusual distribution of the coronary arteries. I shall not inquire how far these two are associated from the point of view of development; we shall only consider the importance of the condition. The vascular anomaly has certainly not been a matter of indifference in itself, although the distribution of the coronary arteries varies considerably; at any rate, I have never seen such a wide-reaching diminution of the region of the right coronary artery. Merkel and Jamin, in their atlas of the coronary vessels, have neither figured nor mentioned a corresponding case. The defect in the tricuspid has apparently caused just as little functional disturbance, for this would not have remained unnoticed, and without injurious consequences as regards the rest of the body. patient had his first knowledge of anything being wrong with his heart only a year before his death, no subjective symptoms at the commencement, but from that the illness developed rapidly, insufficiency of the aortic valves at first being in the foreground, so adding to itself the signs of tricuspid insufficiency, and at last angina pectoris, indicating disease of the coronary vessels.

The heart troubles first began with the disease of the aortic valves after inconsiderable arteriosclerosis of the aorta. Whether it was of syphilitic origin, could not be decided anatomically; that simple arterio-sclerosis may occur under the influence of syphilis, is possible, but there is no necessary genetic connection between them. We shall not discuss this point; what interests us is that the sclerotic process covering only a small space, should attack the aortic valves to an equally small extent, and cause insufficiency. This disturbance set up hypertrophy and dilatation of the left heart, and also affected the right heart, now, the tricuspid, hitherto acting satisfactorily, must have failed much earlier than incompensated failure of the left heart usually causes such trouble. Thus, in the early stage of the disease, the congenital defect of the tricuspid added itself to the not severe disease of the aortic valves, in a fateful manner. For compensation in aortic insufficiency is much more difficult to bring about than in mitral insufficiency, and thus the prognosis becomes very unfavourable when organic tricuspid insufficiency becomes associated with it, which by itself alone does not seriously burden the circulation.

We saw the expression of this in the course of the disease, in the onset with vague "nervous" troubles of a quick development, of a difficult compensation, and the complete absence of any temporary improvement worth speaking of. Finally, independent of the transient symptoms of pericarditis, of which no traces could be found at the autopsy, as the last destructive factor, appeared the anomaly of the coronary arteries, at the moment when the sclerotic process reached the point of origin of theleft coronary artery, the importance of which we entered into; at the same time the blood supply to the muscles of the heart, and above all, that of the septum was jeopardised by the defective development of the right coronary artery. As the clinical reaction of this we saw the angina pectoris, the characteristic symptom of contraction of the coronary arteries, which culminated in attacks rapidly following one another, and paralysing the cardiac muscles before the anatomical consequences of the ischæmia had time to develop.

In how far the assemblage of symptoms in the case described, or its individual features, find analogues in individual experiences or in literature will be little discussed as further exposition will be added, or general conclusions sought for, my demonstration has only the practical aim of a critical consideration of the clinical and anatomical pathological features of a case of complicated disease of the heart, and indeed a school case that teaches us the mutual action of a disposition from internal causes, and an external exciting cause, in which a rapidly destroy ng illness grew upon a soil prepared by congenital foundation out of slight acquired changes, in the germ of which the proteus form of syphilis possibly lies hidden.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Denis Kennedy, F.R.C.S.I., Surgeon to Jervis Street Hospital and to the Children's Hospital, Dublin. Subject: "Intussusception."

### ORIGINAL PAPERS.

RADIUM IN SURGERY. (a)
BY SIR FREDERICK TREVES, BART., G.C.V.O.,
F.R.C.S.ENG.,

Consulting Surgeon to the London Hospital, etc.

At the outset of his lecture, Sir Frederick Treves uttered a word of warning to those who might take a too sanguine view as to the powers of radium. It has appeared to me, he said, as it has appeared to many others, that there is possibly a great future for radium in the domain of surgical therapeutics. I say possibly, because one must exercise the very greatest caution when speaking of the potentialities of new remedies. One is tempted to look too favourably upon them. They are things of great expectations, and sooner or later must be associated with disappointment. I need not remind you of all that was looked for from the X-rays, which were to revolutionise surgery. Well, they have not done so, but they have done marvellous work, very marvellous work, but it is not too much to say we are in sight of the point when the limita-tion of their treatment will be found. The same thing applies to the high frequency current, which was to cure every ill—except poverty. There, again, expectations have not been realised. The same also is true, to a certain extent, of the Finsen light. In

the history of hospital administration I believe there never was a more daring enterprise than the introduction of the Finsen light into this institution. It is quite impossible to express in ordinary language the good it has done. I will not preach any new doctrine; I merely wish to speak about the present position, and to invite you to ask yourselves whether you think we are justified in supposing that the utility of radium is likely to be very great. I do not propose to speak of public cases, but only of patients whom I have actually seen and examined.

It may be said that radium can cure every form of nævus. It can cure the port-wine stain, and I should like to ask any surgeon present whether he has any other remedies that will do as much. can rid the patient of the pigmented mole and the hairy mole. Let me take the case of an infant with a nævus the size of a gooseberry on the top of his head. This was cured by a comparatively short application of radium. In another case a girl was suffering from an angioma on her eyelid in size equal to a plum. It has been subjected to four operations, which proved of little use. By radium it was removed. Perhaps the most theatrical case was that of a young woman who had an angioma which covered practically the whole of one side of her face. She had been subjected to innumerable operations, without any success; under radium treatment she was cured. You may say, but these are all affections of the skin. That is so. I will now tell you of a fibrous angioma, which grew to the size of a hen's egg, in a boy's arm. In this case the skin was perfectly sound. After treatment with radium for four weeks it was dispersed. That a solid mass of that magnitude should have entirely vanished in four weeks is marvellous.

Turning to another part of his subject, Sir Frederick continued: It is safe to say that there is a relation between the amount of radium used and the amount of good done. At the present moment we have only small quantities, but we are dealing with a substance that may be regarded as almost limitless in power. This cannot be said of the X-rays or Finsen light. From the fact that this relation exists, we may draw the conclusion that, so far as growths of a certain type are concerned, if only you have sufficient radium you can carry out whatever may be the wishes of the surgeon.

The effect of radium on chronic eczema is well known. Nothing is more curious in the use of radium than the manner in which it cures, and apparently permanently cures, itching. How it does so is a matter which is under consideration. I will say nothing of vanishing glands. In cases where radium has been used on the face, glands in the neck have disappeared. It would, however, be unsafe to draw any conclusion. As regards rodent ulcers, we may say that those of a certain type may be cured by radium. One case in which the ulcer was of many years duration, and in which the tissue had adhered to the bone, was unsuccessfully treated by the X-rays and the Finsen light. A cure was, nevertheless, effected in two sittings with radium, each sitting lasting an hour. I lay stress on this case because it is said that radium only acts by means of its X-rays, but here is an instance of a cure of a complaint which refused to yield to X-rays.

We may ask ourselves—are these results permanent? They apparently are, but, of course, no very great time has elapsed. I think there is enough on which to base our belief in the utility of radium.

Sir Frederick showed a tube of radium of the value of £800. If radium, he added, ever sank to such a degree of cheapness that it were worth

<sup>(</sup>a) Emeritus Lecture delivered at the London Hospital, January 26th, 1909.

its weight in gold, it would, indeed, be exceedingly

Explaining briefly the nature of radium, Sir Frederick said that it possessed rays of three dispinct kinds, and they were known as the alpha, beta, and gamma rays. The alpha rays contained ions which carried a charge of positive electricity, and were deflected only by an intense magnetic field. They had very little penetrating power, and had relatively slow velocity. The beta rays had ions carrying a negative charge of electricity, and were easily deflected by a magnetic field. Their penetrating power was great, and they moved at a very high velocity. The gamma rays differed very much from the other two classes. They contained no ions, carried no electric charge, were not deflected by a magnetic field, and they possessed enormous penetrating power. Their velocity was equal to that of light. In surgery some of these rays were very harmful, while others were highly useful; it was, therefore, necessary to be well acquainted with them. The alpha and the beta rays were separable, but it was impossible to get beta rays without gamma rays. It was interesting to note the relative penetrating power of the three rays. The alpha series, which would barely penetrate a thick sheet of notepaper, might be taken as 1. The beta rays would then be 100. They would just penetrate a centimetre of lead. The gamma rays would be 10,000. They could easily pass rays would be 10,000. through an inch of steel.

The next business, continued Sir Frederick, was the application of the radium. It was absolutely necessary that it should be applied from a flat surface. To attempt to do so from a tube was ridiculous, because the operator, not knowing the proportion of the alpha, beta, and gamma rays, had not the faintest idea of what he was doing. The radium was upon a flat surface, fixed to the end of a short handle. Of one the surface was a little bigger than a postage stamp in size, and contained 90 milligrammes (1.35 grains) of radium. The cost of it was £360. Of another the surface was circular in shape and about one-third of an inch across. The value was £160. Instruments of other shapes are used for applying radium in-

Continuing, the lecturer said that the patient who underwent the treatment did not merely sit in an armchair while someone held some radium near him. It was necessary, first of all, to have a prescription setting forth the proportions of the various rays. The utmost care had to be taken in determining how far from the affected part the radium should be held, and for how long the treatment should be continued. It is a strange treatment, he said. You may apply it on Monday, and it may appear to have no effect, and on Tuesday with the same result, on Wednesday, and on Thursday. On Frida perhaps for the first time, it will begin to react. On Friday,

Other matters in connection with radium and the treatment of disease were also occupying attention. There was the question as to whether tuberculous disease of the lungs could be cured by inhaling the emanations from radium. Another point was whether the injection of a radio-active colution by means of a hypodermic syringe would be beneficial in certain cases. He had been dealing solely with cases in his own experience, but with this reservation he gave the experiment of a brother scientist of high reputation. A cancer had been set up in a mouse, and a solution of radium was injected, with the result that the growth disappeared. In conclusion, Sir Frederick once more begged his medical friends to be cautious as to the way they spoke of permanent cures,

### INFANTILE MORTALITY AS SEEN IN A CHILDREN'S HOSPITAL. (a)

By DAVID FORSYTH, D.Sc., M.D. Lond., Assistant Physician to Charing Cross Hospital : Senior Physician for Out-Patients, Evelina Hospital for Sick Children.

An exact pathological knowledge of the causes of infant deaths is of the greatest practical importance from the point of view of prevention. Hitherto our principal guide in this matter has been the official returns of the Registrar-General, which show the relative importance of various diseases in this connection. These returns, however, are in some cases difficult to harmonise with the experience in the wards and post-mortem room of a children's hospital. Conditions which are known to be frequent causes of death in hospital practice occupy only a relatively insignificant place in the official returns, whilst others which are officially important are, in practice, unimportant. With the object of obtaining statistics based on accurate death-certification, Dr. Forsyth examined the death records of the Evelina Hospital for Sick Children, from January 1st, 1885 to December 31st, 1906, and analysed the causes of 1,202 consecutive infant deaths under one year. The numbers in this series were as follows:

c as lullows				
Acute lung disea	ses		 	254
Diarrhœa			 	188
Whooping-cough			 	135
Tubercle			 	128
Marasmus			 	78
Congenital defec	ts		 	75
Syphilis			 	55
Septic conditions	s		 	44
Intussusception			 	34
Mastoid disease			 	32
Meningitis (non-	tubei	culous)	 	26
Rickets		••	 	13
Convulsions			 	13
All other disease	s		 	127
			1	,202

The method adopted in tabulating these cases was explained, and reasons were given to show that a comparison with the returns for England and Wales was permissible. For reasons specified, the three items, prematurity, measles and whoopingcough were excluded from the comparison. Under the remaining headings, the mortality in the official and in the Evelina Hospital returns strod thus in percentages :-

I			Evelina Hospital.	England and Wales.
Acute lung disease	es		 23.8	21.4
Diarrhœa			 17.6	23.2
Tubercle			 12.0	5.1
Marasmus			 7.3	16.3
Congenital defect	s		 7.0	6.3
Syphilis			 5.2	1.3
Septic conditions			 4.1	
Intussusception			 3.2	
Mastoid disease			 3.0	_
Meningitis (non-to	abero	ulous)	 2.4	2.0
Rickets		••	 1.2	0.58
Convulsions			 1.2	12.2
Injury at birth			 	0.76
Starvation			 	0.7
Other causes			 12.0	10.16
			100.0	TOO 0

Whilst a fairly close correspondence exists between the two series many striking differences must be noticed. Acute lung trouble and congenital defects

<sup>(</sup>s) Abstract of Paper read before the Royal Society of Medicine' an, 22nd, 1909. For discussion se page 000.

show no great divergences. With diarrhoea the somewhat smaller figure that represents the Evelina Hospital mortality is accounted for by two facts: In the summer, when diarrhoea is rampant, the accommodation in children's hospitals is overtaxed, and even moribund cases may be sent away; secondly, it is probable that some of the deaths in the official returns which have been ascribed to diarrhœa would have been registered under other headings if facilities for post-mortem examinations were as great in general practice as in hospitals. With regard to marasmus, a difference of more than 100 per cent. exists between the two series of figures. Since the official return represents over 15,000 dead infants, its interpretation possesses wide practical importance. Marasmus is a term of vague significance and is often employed in connection with conditions of which it is merely a symptom, especially with syphilis, improper feeding and tubercle. It cannot be doubted that deaths from these causes are sometimes registered as due to marasmus, and that a proportion of them should be distributed under other headings. These criticisms apply even more forcibly to deaths from "convulsions," the official returns for which are no less than 1,000 per cent. of the Evelina figures, and represent 11,000 deaths. The term convulsions under no circumstances represents more than a symptom, and when employed as a cause of death merely hides under a meaningless designation important fatal conditions, the returns for which are unduly minimised.

With regard to syphilis, this disease was held responsible in 1905 for only 1,200 infant deaths in the whole of England and Wales—little more than three a day. In the same year, however, 19,000 infants under two months are stated to have died from prematurity. Probably this large figure included the deaths of numbers of syphilitic infants. As a matter of fact, the deaths in 1905 from syphilis of infants under two months amounted only to 300 according to the official returns. Other deaths from this cause must be looked for under the heading "marasmus." With regard to rickets, the hospital figures are twice those for England and Wales. Here we must remember that cases of rickets are often fatal from broncho-pneumonia or diarrhœa, and the primary condition is likely to

be overlooked.

After referring to acute mastoid disease as a cause of infant mortality, Dr. Forsyth passed to the question of tubercle. The Evelina Hospital figures included only those cases in which tubercle was the actual cause of death, and excluded all in which, though a tuberculous lesion was found post-mortem, death resulted from some other cause. The dif-ference in the two series was probably to be explained by the tendency of tuberculous disease in infants to simulate other non-tuberculous affections. Probably the hospital figure, 12 per cent., more nearly represents the real mortality than the official figure, 5 per cent. The frequency, however, with which life is destroyed by tuberculous infections incurred during infancy is under-estimated even by this larger number, because many such cases do not die until their second year, and their deaths do not come into the infant mortality returns. The full importance of tubercle as a factor in infant life would be better revealed by statistics dealing with deaths between one year and fifteen or even eighteen months. At the Evelina Hospital fifty children died of tubercle between these ages. Many, if not most of them, must have been infected during their first

In conclusion, Dr. Forsyth expressed the hope that these Evelina Hospital statistics would lead

to the preparation of corresponding figures from the records of other children's hospitals. An accurate knowledge of the causes of infant mortality can be best obtained from those institutions in which special opportunities exist for ascertaining the exact causes of infant deaths. If, further, the absolute numbers in each series are published, we shall be in a position to draw valuable conclusions based on many thousands of cases. At present 20 per cent. of the mortality, representing 25,000 deaths, is attributed to vague symptoms. When the community has set a proper value on infant life, such terms as "convulsions" and "wasting" will no longer be accepted for death-registration. If no more satisfactory explanation of the cause of death is forthcoming, further steps will be insisted on, as is done to-day with adult deaths. By this means a far-reaching and practical measure will be taken to diminish the present excessive waste of infant

### REMARKS UPON

### SOME GONORRHŒAL DISEASES OF THE EYE. (a)

By SYDNEY STEPHENSON, M.B., C.M., F.R.C.S.E.,

Ophthalmic Surgeon to the Evelina Hospital, the Queen's Hospital for Children, and Queen Charlotte's Hospital.

(Concluded from page 86.)

3.—OPHTHALMIA NEONATORUM.

Or the gonorrhœal affections of the eye, ophthalmia neonatorum is incomparably the most important both from a sociological and a medical point of view; first, because it is relatively often met with, and, secondly, because it is by far the most frequent cause of preventable blindness. At the same time, the best recent statistics appear to show that ophthalmia neonatorum is becoming less frequent. That is cerneonatorum is becoming less frequent. That is car-tainly the experience of most ophthalmic surgeons. Still, that the disease should prevail at all nowadays, when its prevention is so well understood, is little less than a scandal and a reproach to all concerned. fact can scarcely be too strongly insisted upon that a case of ophthalmia neonatorum implies that somebody is to blame. The time has come for plain speaking. I believe that no great progress will now be made in preventing ophthalmia until we are prepared to saddle somebody—be it midwife or medical practitioner—with the responsibility for practically every case of the disease. Let us press this question of personal responsibility home, and we shall assuredly hear less of ophthalmia neonatorum in the future than we have in the past.

Every case of ophthalmia neonatorum is due to the transference (direct or indirect) of infective secretions from the genitalia of the mother to the eyes of the child. This process sometimes comes about at the moment when the infant's head is passing through the introitus, and, as insisted by Mules many years ago, the stretched perinæum plays no inconsiderable ago, the stretched perinaum plays no inconsiderable part in the transference of infection. Another commoner way of infection takes place after the birth of the child, when infective secretion clinging about the lids and lashes is carried into the conjunctival sac by the fingers or blinking of the baby, or by the water, towels, sponges, or other articles used in the first bath.

It cannot be questioned that the eyes may also be infected with the germs of disease while the child is as yet in utero. Many such cases have now been recorded. Thus, in my recent monograph (6) I collected 105 cases—namely, ro of my own and 86 reported by other observers. The current explanation of these cases of so-called "congenital ophthalmia," which we owe to Haussmann (7), is that the membranes have ruptured many hours before the birth of the baby, with the consequence that the gonococci or other causative micro-organisms were enabled to gain entry to the conjunctival sac of the baby, where pos-

(a) Based upon a Clinical Demonstration given at the Polyclinic, ondon, on May 8th, 1908.

sibly the special circumstances hastened and fostered the appearance of the symptoms of ophthalmia. Powerful adjuvant factors were to be found in digital examinations, the application of instruments, or the administration of douches. Haussmann's view has been adopted very generally. But, as I have pointed out elsewhere (loco citato), a careful analysis of the published cases shows that is by no means generally applicable. Premature rupture of the membranes applicable. Fremature rupture of the membranes of ante-partum ophthalmia. The time of rupture of the membranes is mentioned in 71 of the 86 cases spoken of above. The rupture was premature spoken of above. The rupture was premature in 26 of these cases. But in 45 (63.38 per cent.), less than the minimum incubation period of the gonococcus, which I have set down as 24 hours, elapsed between the rupture of the membranes, on the one hand, and the discovery of the ophthalmia, on the other. It is therefore certain that the Haussmann theory, while accounting for some cases, does not account for anything like all the reported instances of ante-partum ophthalmia. The evidence points in the ante-partum ophthalmia. The evidence points in the direction of micrococci being able, under circumstances with which our acquaintance is still imperfect, to penetrate the intact membranes.

Infection of the eyes during passage through the vagina seems improbable under ordinary circumstances, since the junction between the lids, besides being sealed with vernix caseosa, is practically watertight. Nevertheless, it could occur during digital examination, the application of forceps, or, indeed,

anything that caused displacement of the eyelids.

The term "secondary infection" is applied to cases of ophthalmia due to contamination of the eyes some time after birth, such as may take place by the fingers of an uncleanly mother or careless nurse. My personal experience teaches me that a bacteriological examination of the mother's secretions, particularly those from the urethra or the cervical canal, will generally bring to light in these cases of secondary infection the cause in the shape of genococci. Other instances of secondary infection are to be found in one baby inoculated from a second suffering from ophthalmia, or from a nurse or attendant herself affected with gonorrhea. Sonden observed an epidemic of ophthalmia neonatorum, in which gonococci were found in two of the mothers only, and Max Knies, (8) in quoting this case, mentions an epidemic which occurred in the practice of one midwife, who was presumably herself the source of infection. Charbonnier and le Roux (9) saw a gonococcal ophthalmia in a baby of 13 days, and they incriminated the water used in the baptism of the infant as the means whereby infection had been conveyed. A. Pinard's experiences (10) of secondary infections have been of an interesting nature. He had found at his clinique that certain nature. He had found at his cinique that certain foster-mothers, whose own babies were healthy, when allowed to tend other babies, managed somehow or other to pass infection, and thus to start small epidemics of ophthalmia. The little outbreaks were at once suppressed when those women were replaced by others of a more intelligent and careful character.

It has been assumed, in my opinion upon insufficient evidence, that late cases of ophthalmia are mild cases of ophthalmia. Taken collectively, primary are doubtless more to be dreaded than secondary infections, but that is a different matter from claiming, as some have done, that secondary infections in detail are of a mild character. Crede recognised the existence of isolated dangerous cases of secondary ophthalmia (11). As pointed out by Bumm, Krönig, and Steinbuchel, the lochial discharges furnish a favourable medium for the development of the gonococcus. It has been stated by Fruhinsholz (12) that gonococci may often be found for the first time after delivery, having been overlooked even during the later stages of pregnancy. "All investigators," wrote Prince A. Morrow (13), "who have had occasion to examine the lochial fluids, agree in attesting that there is an extraordinary multiplication of the gonococci even as early as the second day." These observations go some way towards explaining why a woman with latent gonorrhoea may not infect her baby's eyes during parturition, and yet may do so during the puerperium by means of the lochia. It appears, indeed, that the maternal infectivity increases during the puerperium owing to multiplication of gonococci in the lochial

fluid during the first few days after labour.

The matter may be summed up by saying that the powers of infection stand in direct ratio to the amount of secretion and to the number of the gonococci, and in inverse ratio to the care exercised by the mother, nurse, and medical attendant.

So much for the actual mechanism of infection. Now, as to the causative agents of infantile ophthalmia, two propositions stand out clearly: first, that the agents in question are identical with the micro-organisms found in the unhealthy maternal passages; and, secondly, that most of them have on occasion been found in the male urethra.

It is important to bear in mind that although nearly all destructive cases of ophthalmia neonatorum are due to and caused by the gonococcus, yet, even in hospital practice, that organism can be found in about two-thirds of the cases only. It is also a noteworthy point that no micro-organisms whatever can be discovered in about 15 per cent. of all cases. Cramer (14) has suggested that such amicrobic forms may be due to injuries sustained by the conjunctiva while the baby is still in utero. Many of them, in my experience, are merely premonitory or concomitant signs of con-genital syphilis. Wertheim (15) has pointed to the existence of degenerated forms of gonococci, which retain their pathogenicity despite the fact that they no longer stain properly. Wertheim's observations are obviously of importance from the present standpoint.

It may be stated in round numbers that of every 100 cases of ophthalmia neonatorum, 65 per cent. will be associated with gonococci, 10 per cent. with pneumococci, 5 per cent. with bacillus coli, 5 per cent. with other pathogenic micro-organisms, and, finally, that in 15 per cent. the bacteriological findings will be negative.

Another point of practical importance is that most cases of ophthalmia in the baby originate from a latent gonorrhea in the mother. It is probable, according to Neisser, that most cases of ordinary acute gonorrhea are contracted from chronic cases (C. F. Marshall) (16). As regards ophthalmia, of 20 women with ophthalmic babies, Groenouw (17) observed pain during micturition in 15 per cent. only of the cases, despite the fact that all the women suffered from vaginal discharges which contained gonococci. Of my own cases, a history of profuse genital discharge and scalding during micturition and local discomfort was obtained in 17 per cent. only. In another 50 per cent. the history was merely of a slight fluor albus. In many of the latter and in some of the remaining cases, which formed 33 per cent. of the total number, the underlying condition was probably a specific endometritis or endocervicitis, the organisms producing which had remained latent until roused into activity, as we now know they may be, by the complex nutritional processes involved in child-birth.

The facts detailed above seriously weaken the position of those who recommend, as Dr. Peter Horrocks (18) has recently done, that in the absence of obvious signs of acute gonorrhea in the mother, the baby's eyes should be left alone. If the symptoms of latent gonorrhea cannot be detected even by a or latent gonormoze cannot be decreted even by a skilled gynæcologist, it is too much to expect that a midwife could do so. Personally, I am convinced that we shall not do our duty as medical practitioners unless we adopt some preventive measure in every case of labour, no matter what social position the mother may happen to occupy. It is no part of my present intention to enter deeply into the question, although obviously such measures will naturally fall into one of two groups, namely, phophylaxis as it affects— (1) the mother, and (2) the child.

(1) Prophylaxis in the mother.—It would seem

reasonable to douche the vagina with some weak antiseptic lotion, as lysol, from time to time during the progress of the labour; but this practice, I understand, has not the approval of most accoucheurs. The objection to the employment of the douche under apparently normal circumstances is obvious even to one who, like myself, possesses no expert knowledge of the subject. But such objections could scarcely apply to a woman who was affected with a profuse coloured

discharge, which all experience pointed out as being of a gonorrhoeal nature. Still, even then, the douche could not be expected to remove all sources of infection, as, for example, from gonococci embedded in the cervical glands. It could, at best, merely reduce the chances of infection, without affording any real security that the baby's eyes would remain free from

The fallacies of the vaginal douche as a means of preventing ophthalmia are shown by the figures given by Credé and Bayer respectively. The former observer by Credé and Bayer respectively. The former observer used the douche in 60 women believed to suffer from genorrheea, but the babies of 14 of these women nevertheless developed ophthalmia. In spite of antiseptic douchings, Bayer (19) still had from 12.9 per cent. to 14.3 per cent. of ophthalmia.

Considerable importance has been attached by K. Menge (20) to the acidity of the normal vaginal secretion, known to be replaced during menstruation and child-bed by a copious alkaline discharge, in which pathogenic micro-organisms find a suitable habitat. Döderlein has suggested the prophylactic use of lactic acid under such circumstances as a means of restoring the normal acidity of the secretion.

The careful cleansing of the pudenda of parturient women by a suitable antiseptic lotion, as sublimate or lysol, will obviously tend to reduce the likelihood of ophthalmia in the baby. It should never be

neglected.

(2) Prophylaxis in the baby.—It cannot be doubted that preventive measures are more likely to succeed when carried out in the baby than in the mother. We have here a choice of methods, namely, the aseptic and the antiseptic. The aseptic plan is distinguished by its extreme simplicity. It merely requires that the skin of the eyelids and the lashes be freed from adherent secretions by repeated wipings with morsels of damp absorbent wool as soon as the head is born. The figures are quite conclusive as regards the value of these simple means. For example, among 1,000 babies treated in this way, Korn (21) had only three cases of ophthalmia. The offspring even of mothers who suffered from granular vaginitis or other evidences of gonorrhoal infection remained free from ophthalmia. Simeon Snell's experiences (22) were much to the same effect. During a period of three years, 2,242 labours took place in the Jessop Hospital for Women, Sheffield. In the first 200 labours there were a few cases of ophthalmia, but in the last 2,000 not a single case occurred. The antiseptic plan of prophylaxis consists in dropping some chemical agent in the eyes as soon as maybe after birth, in order to destroy any infective material that may already have gained admission. The type of all such agents is the 2 per cent. silver nitrate recommended, in 1881, by Professor Karl S. F. Credé, of Leipzig (11). As soon as possible after birth the baby's eyelids were gently separated by an assistant, and a single drop of the silver was placed in each eye. Nothing further was done. Babies treated by these means collectively remained free from ophthalmia, despite the fact that many of the mothers manifested vaginal blennorrhea and trachomatous colpitis. During a period of nearly three years, 1,160 babies were born alive, and amongst that number one case (at most two cases) of ophthalmia occurred. Large collective figures dealing with the Credé method have been published by several writers, as Haab (23), Köstlin (24), and myself (6). These testify in the most striking way to the success of the Credé plan. The figures are included in the following table:-

	No of Live Births.	Percentage of Ophthalmics	
I. Haab (1886)	. 10,521		1.0
2. Köstlin (1898)	. 24,724		0.655
3. Stephenson (1907) .	. 51,728		0.751

Strenuous objections have been raised to anything like a general adoption of the Credé plan, usually from sentimental reasons. The more tangible objections are three in number:—(1) Conjunctival catarrh; (2) conjunctival hæmorrhage; and (3) corneal opacities or ulcerations. The truth of the matter seems to be that the plan is harmless except for the fact that it is often, perhaps generally, followed by temporary con-

junctival reaction, called by the Germans argentumkatarrh. The reaction, as Credé himself pointed out, is more pronounced in premature than in term infants. Cramer's bad results (25) have not been confirmed, and there is, indeed, a large body of evidence directly opposed to his experiences.

Does the use of the Credé plan invariably prevent the development of ophthalmia? No! It cannot protect against ante-partum infection, nor against infection after the drops have been put into the eyes. A great deal, too, depends upon the way the silver is used, a point on which G. Leopold (26) has laid great stress. All this will be admitted by every impartial observer. At the same time I am convinced that Dr. Peter Horrocks's recent statement (18), which was to the effect that "where there is a gonorrhoea in the mother a single application of a germicidal solution used as a routine measure will not prevent ophthalmia," is far too absolute. It would be interesting to know the evidence upon which so sweeping a statement is made. Such facts as I know of all point in the other direction. For instance, among 816 babies treated by the Credé plan by Zweifel (27), two alone developed ophthalmia, although 61 of the mothers were known to be affected with gonorrhoza. There would be no difficulty in quoting other figures that tell substantially the same tale.

Many attempts have been made to find some anti-

septic agent that would be as efficient as, but less irritating than, the 2 per cent. Credé solution. There is now a practical unanimity of opinion among those best qualified to judge, both in England and America, that in a 1 per cent. solution of silver nitrate we have such a remedy. Among 18,393 babies treated with the 1 per cent. solution, the morbidity of ophthalmia was o.628 per cent.—that is to say, slightly lower than when the Credé solution was employed. It is to be remarked, however, that the latter was used in a much larger number of babies (51,728). But the figures are large enough to exclude any serious statistical fallacy. As matters stand, there need now, in my opinion, be no hesitation in substituting the r per cent. for the 2

per cent. solution of silver nitrate.

To sum up the gist of my remarks on ophthalmia neonatorum, I would say:—

(1) That all cases of ophthalmia in the baby are

due to the direct or indirect transference of infective secretion from the mother to the child.

(2) That such transference may be primary, at or about the time of birth, or secondary, some days or longer after birth.

(3) That gonococci are present, and can be demonstrated in about two-thirds of all cases of ophthalmia

(4) That the causal micro-organisms of ophthalmia, be they gonococci or not, can be found in the female genitals and the male urethra.

- (5) That acute gonorrhœa is not common in the mothers of ophthalmic babies, the underlying infective condition usually being a latent gonorrhœa.
- (6) That some form of prophylaxis should be adopted in every case where a woman in labour is attended by a medical man or midwife.
- (7) That a r per cent. solution of silver nitrate is an efficient and relatively non-irritating antiseptic, for use to babies' eves.

### CLINICAL RECORDS.

### TWO CASES OF APPENDICITIS.

BY JOHN ALLAN, M.D.EDIN. APPENDICITIS is nowadays a comparatively common

disease, and is undoubtedly more frequently met with than formerly. From a study of the medical and surgical records of our predecessors, one cannot but conclude that the disease presents in our time a more virulent type, and that the assistance of the surgeon has become a matter of greater necessity. The following two cases are instructive, and not without interest.

CASE I was that of W. T———, a man, æt. 47. Case I was that of W. T——, a man, æt. 47. The history was that nine days before his admission to hospital he was attacked with sickness and vomiting, and he suffered from general abdominal pain, which later became localised in the right iliac region. After a few days these acuter symptoms apparently subsided. The bowels, however, remained confined, and aperients, enemas, etc., were tried without avail. Three days before his admission to hospital vomiting again started, was frequent, and finally became fæculent in character. The abdomen became enorfæculent in character. The abdomen became enor-mously distended. Nine days after the commencement of the first symptoms he was persuaded to go to hosof the first symptoms he was possible to a.m. He was pital. He was admitted about 10 a.m. He was brought to the hospital in a cab, and on the way he with severe abdominal pain. On had been seized with severe abdominal pain. On admission he still complained of the pain (the acuteness of which had considerably diminished); his pulse was imperceptible, his respirations were rapid, his face and extremities were cold, and he was covered with a cold, clammy sweat. After being in bed for a little over an hour, he had improved somewhat. His pulse was 140 per minute, but very feeble; respira-tions, 50 per minute; and the temperature was 97° F. The tongue was furred and dirty, the mouth parched, and the breath very foul. The abdomen was distended and tympanitic, and he was bringing up mouthfuls of fæcal vomit very frequently. After rallying, the patient felt quite happy, and laughed and talked with his friends, and he had no conception that he was in a very serious condition. In the afternoon, about 3.30, the rally was thought to have reached its acme, and it was considered that the time for operation (if any was to be done), was then the most favourable that one could expect. The abdomen was therefore opened, and the condition found was dreadful. The appendix was gangrenous, and the gangrene had spread, the cacum to the extent of about three inches being also involved. Close to the base of the appendix the cacum had given way (probably in the morning, when the patient was going to hospital in the cab), and faces were passing into the abdominal cavity. There was enormous distension of the gut, but there was no actual peritonitis. Resection of the gangrenous areas plus anastomosis was out of the question, owing to the patient's condition. Indeed, as soon as the

patient was sufficiently under the anæsthetic to allow the surgeon to proceed with the preliminary steps, it became necessary to dissect out the median basilic vein and give normal saline intravenously. The gangrenous portion was rapidly excised, and the ends quickly sutured to the abdominal wall, after the fashion of a colostomy. The abdominal cavity was washed out with normal saline, drainage established, and the wound speedily closed. The patient soon recovered from the effects of the anæsthetic, and he recognised his relations and maintained a happy attitude to the end, which came about 8.30 p.m.

CASE 2 was that of Mrs P--, a woman, æt. 41. The history was that two days prior to her admission to hospital, she was seized with abdominal pain, etc., the symptoms pointing to an acute attack of appendi-The medical man called in had ordered sulphate of magnesia, and after the administration of this the bowels acted well. On admission she complained of pain (not very severe) over the appendix region. There was slight tenderness on pressure, with some resistance on palpation, over the right iliac area. The pulse rate was 100 per minute, and the temperature was 99.40 As no morphia had been given, the clinical symptoms did not give one the impression of any very serious mischief, only the patient's facial expression was not quite in accord with a mild attack. It was decided to wait until the next day, and in the interval a leucocyte count was taken, and this registered 37,400 white cells per cm. At the operation the appendix was found perforated, and there was a small abscess (about halfa-teaspoonful of pus). Convalescence was interfered with by an attack of ether pneumonia, but, so far as the appendix condition was corcerned, it was quite She was discharged five weeks after uninterrupted.

her operation.

On examining the above two cases, there are several points worthy of notice. In Case I we have exemplified an extreme case and one that will rarely be seen, but it well illustrates the danger of leaving cases too long and the grave character of recurrent vomiting, which becomes fæcal. In justice to the medical practitioner in attendance, it should be mentioned that he twice advised the patient to go to hospital, without success, so that the blame was almost entirely the patient's. Vomiting, as an initial symptom, is present in a considerable number of acute appendicitis cases, but it will disappear in about 48 hours in favourable cases. Its persistence, or, still more, its return after having temporarily ceased, should always put one on guard, as this almost certainly means that there is some grave pathological change in the appendix, such as perforation, gangrene, etc. Another unfavourable point in Case I was the complete obstruction of the bowels. Associated with appendicitis there is generally constipation, and not infrequently there is meteorism during the acute attack, but total obstruction from paresis of the gut is only met with when there is grave mischief of the appendix. An interesting point in connection with this case also, was that the pulse was imperceptible for about two hours before death, although the patient retained consciousness and was able to chat and laugh to within half an hour of his death. This failure of the pulse some hours before death is occasionally observed in severe toxæmic conditions.

toxemic conditions.

With regard to Case 2, interest centres round the examination of the blood. Here we have a case, presenting a typical picture of a definite, but not very acute, attack of appendicitis in which an enumeration of the white blood corpuscles gave a clue as to the nature of the attack. I am of opinion that the leucocyte count is, generally speaking, of most value in those cases of appendicitis where there are small deep-seated abscesses, as in such cases it is often impossible to determine by physical examination whether or not there is a collection of pus. In appendicitis where perforation or gangrene of the appendix occurs, and where there are necrotic changes, the rule is that leucocytosis is very marked, and associated with these cases minute abscesses (often not amounting to more than a few drops of pus) are quite commonly found.
The abscesses, though small, are generally very virulent, and provided that the patient is not overwhelmed by the toxic products, the leucocyte increase is enormous. When one realises that the clinical symptoms in such cases are often misleading, it is easily understood why an examination of the blood is so valuable in determining for or against operation.

### OPERATING THEATRES.

GREAT NORTHERN HOSPITAL.

TUBERCULOUS PERITONITIS .- MR. PEYTON BEALE operated on a woman, æt. 30, who had been admitted with the following history: For the last three years she had suffered from very acute abdominal pain, which was particularly felt directly she changed from the recumbent to the upright posture. Its origin was evidently intra-abdominal, and when she was lying on her back she was obliged to support the abdomen with both hands and to press it firmly. This she continued to do for five or ten minutes after assuming the erect posture. She had been under the care of Dr. John Wood, of Deal, who had been watching her for a considerable period, and who had absolutely eliminated the possibility of the pain being hysterical. Sometimes the pain remained for some hours in the epigastric region. Beyond some slight dyspeptic symptoms, the patient complained of nothing else. There was no trace of any hernia, nor was the abdomen lax or pendulous. The past history of the patient was unimportant, except that there was a tuberculous family history. The pain worried her so much, and was increasing in secret, that she readily consented to an exploratory operation. When she was under an anæsthetic, a mass about the size of an orange could be felt supposedly behind the stomach, and there was also some thickening and increased resistance in the appendix region. An incision was made to the right of the middle line of the abdomen, and on introducing the hand a mass of enlarged glands was felt at the back of the mesentery, reaching downwards as far as the level of the umbilicus and upwards as far as the diaphragm. The duodenum seemed to be embedded also in them; some were soft, others calcareous. The mesenteric glands were investigated; some were found eniarged, and were like tuberculous glands. There were also structures which seemed like tuberculous glands behind the cæcum, and there was a little clear fluid in the peritoneal cavity. As there was nothing more to be done, the abdomen was closed.

The patient did very well for about a week, and was see from pain. Then a part of the wound opened, free from pain. Then a part of the wound opened, and some greenish yellow pus was discharged. It was supposed that some of the soft abdominal glands had broken down, and so caused the discharge. She did fairly well for some time, but then developed several inflammatory areas on the surface of the abdomen. These, on being opened, were found to be typical tuber-culous "abscesses." They did not heal, but, on the contrary, each one became a tuberculous ulcer with very marked undermined edges. The patient was becoming thinner, and very soon the temperature began to rise, and she had night sweats. Then the abdomen began to enlarge, and she vomited frequently, and it became clear that she had some slight intestinal obstruction. The abdomen was therefore again opened in the middle line, and was found to contain a good deal of thin, yellowish-green fluid, such as is com-monly found in tuberculous peritonitis; there was also some recent lymph amongst and upon the coils of intestine, and a large pocket of fluid below and behind the liver. The abdomen was freely irrigated with hot salt solution, and the patient appeared none the worse

for the operation.

Mr. Beale said that the pain in this case was a curious feature. Such pain was commonly associated with pendulous abdomens, and with ventral and other herniæ, but he had not come across it before in any cases of abdominal tuberculosis. There was no doubt about the pain and its severity. The history of the case after the first operation goes, he thought, to show that the patient's tubercle was kept under control while she was living on the south-east coast, but when she came to London the tubercle gained the upper hand, as shown by the local lesions in the abdominal wall and

by the spread of the disease within the abdomen. He expected that general tuberculosis would supervene very soon, and the prognosis he considered very bad. It was, of course, possible that there was a bacillus coli infection of the glands as well, which might have accounted for their breaking down after the first opera-The abdominal fluid removed at the second operation would be investigated to see if it contained bacillus coli.

FEMORAL HERNIA.—The same surgeon operated on a woman, æt. 70, who had been admitted with acute intestinal obstruction of one week's duration, with fæcal vomiting of two days' duration. The symptoms had come on gradually during the previous week, and absolutely no history of sudden strain or of anything to account for the condition could be obtained, nor had she suffered previously from any similar attack. She had been under the care of a doctor, who had repeatedly examined her without finding anything to account for the obstruction. The vomiting came on about every half-hour or twenty minutes, quite suddenly, and with little or no effort, and the patient was remarkably well considering the completeness of the obstruction. Nothing had been passed by the bowel for six days. On admission the abdomen was slightly distended; no peristalsis was visible, nor could any tumour be felt. It seemed as if the obstruction was in the small intestine rather than in the large, and the symptoms were just such as might be expected in a case of strangulated hernia. The femoral, inguinal, ventral, and all other regions were carefully examined, but the only thing to be felt was some enlargement of the glands in both groins. The patient was anæs-thetised, and a median laparotomy performed. On introducing the hand into the abdominal cavity, the parietes of the cavity were first examined, and when the hand reached the right inguinal region a knuckle of small intestine was immediately felt protruding through the femoral ring. On examining the right groin with the other hand, and making gentle traction on the knuckle of bowel inside the abdomen, it was observed that there was just a slight wrinkling of the skin in the region of the saphenous opening, but even then there was no protrusion or tumour to be felt in that region. By gentle traction upon the bowel by the hand within the abdomen, and by taxis in the groin by the hand outside, together with flexion of the right thigh, the knuckle of intestine was released and was brought outside the abdomen. It was purple in colour, with a very marked constriction, and on its being exposed to the air for a few minutes it became evident that it could be safely returned. The House Surgeon then completed the operation by stitching up the abdominal wound and applying a dressing.

Mr. Beale remarked that this was one of those femoral herniæ in which simply a knuckle of small

intestine was strangulated, only just sufficient to cause complete obstruction; practically none of the mesentery was strangulated. Although the patient was thin, there was no external evidence of a femoral hern a, and its presence could not be ascertained from without even when the groin was examined with the expectation of finding a hernia. The symptoms presented by the case were significant of complete obstruction of the small intestine.

### TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD FRIDAY, JANUARY 22ND, 1909.

Dr. PORTER PARKINSON in the Chair.

THE CHAIRMAN showed a case of

RHEUMATOID ARTHRITIS IN A YOUNG CHILD. Dorothy G., æt. 21, began to suffer from swollen and painful joints in June, 1908; the ankles and wrists were first affected, then the knees, elbows, and other joints. There was much pararticular swelling with excess of fluid in the joints. The joints were at times

acutely painful, and the temperature rose occasionally to 103° or 104°. There was much wasting, and the to 103° or 104°. There was much wasting, and the child had a pallid, earthy tint of skin, and appeared to be suffering from a slow toxæmia. There was general enlargement of the lymphatic glands, especially in the The spleen was much enlarged, axillæ and groins. extending four finger-breadths below the costal margin. Over parts of the trunk and legs was a diffuse brown pigmentation resembling that seen in adults suffering from the same disease. The lungs and heart were normal. There was extreme wasting of the muscles of the legs and forearms. Intervals of apyrexia alternated with fever often up to 103° F., or higher, lasting for a week or so, during which the joint pains and swelling, the lymphatic and splenic enlargements, and the cachexia were all much increased.

There has been great improvement during the last six weeks both in the general and local symptoms.

Dr. E. I. Spriggs said that occasionally, on seeing a case for the first time, there seemed to be some difficulty in diagnosis between subacute or chronic rheumatism and rheumatoid arthritis, though that difficulty generally vanished when the case was carefully gone into. Recently he showed, before the Clinical Section, an adult male with true rheumatoid arthritis, who had enlarged glands in the groin, axillæ, and above the elbow; he also had exophthalmic goftre. In the latter disease there was frequently pigmentation, and in chronic infective arthritis in adults. Exophthalmos had also been described in connection with Still's disease, though he had never seen it. The spleen was probably enlarged in children because that organ responded more easily to infective conditions in them than in adults. He mentioned a case like that of Dr. Parkinson's, in which material had been obtained from the joint, but efforts to cultivate a microorganism were fruitless.

Dr. PARKES WEBER asked whether von Pirquet's re-

action for tubercle had been tried?

Dr. PARKINSON, in reply, remarked that Dr. Spriggs' case of rheumatoid arthritis, in which glands were enlarged, was interesting in showing the link between the cases in children and in adults. He did not think the Dr. T. R. Whipham showed a specimen from a

case of

CONGENITAL CYSTIC DISEASE OF THE KIDNEYS, and a skiagram taken during life. Both kidneys were from a male infant, aged 11 months, who was brought up for whooping-cough and found to have an enlarged abdomen with bulging in both flanks and some dilated The masses could be felt symsuperficial veins. metrically situated, and the anterior edges extended from the costal margin to the middle of Poupart's ligament. The tumours were slightly movable, and the percussion note over them was dull. The liver could be felt 14 in. below the costal margin. abdomen had been noticed to be large since birth. The specific gravity of the urine varied from 1005 to 1010. The urine contained a varying amount of albumin, from 1 to 8 per cent. The quantity of urea was from .4 to 1.8 per cent., the total being from 1.05 to 3.12 grammes per diem. The child, who was not greatly troubled by the cough, became rapidly worse. A transient cedema of the hands and feet occurred for a few days, and towards the end the liver became en-larged and some purpuric spots appeared on the trunk. Death was ushered in by convulsions. The kidneys weighed 7½ oz. each. They were uniformly pale and tough, and showed little difference between the cortex and medulla. They were crowded with innumerable cysts, the largest being the size of a very small pea. The pelves The capsules were somewhat adherent. were dilated and contained a deposit of uric acid sand, but the ureters were normal, and there was no obstruction to the flow of urine.

Dr. PARKES WEBER congratulated Dr. Whipham on having diagnosed the condition during life. In his opinion however, congenital cystic disease was not the only disease which might give rise to enlargement of both kidneys and albuminous urine in a child. He had published a case which showed diffuse lymphocytic growth of both kidneys.

Dr. ROBERT HUTCHISON asked whether congenital

cystic kidneys were ever unilateral, as he had made such a diagnosis in an adult case. He could recall two other cases in which the diagnosis was made during life. If a nodulated tumour could be felt in both loins, and there was suspicious urine, he thought the diagnosis was justified.

Dr. CAUTLEY said he thought the diagnosis could be

justified if only one kidney was felt, as there were several cases on record in which one kidney showed signs and the other was found post-mortem to be also

cystic.
Dr. Forsyth quoted a case in which two enormous cystic kidneys were found post-mortem, but only one had been felt.

Dr. Jex-Blake showed a case of "Fibrosis of the Left Lung," of considerable standing, in a child, æt. 8. There was a history of phthisis on both sides of the family. The patient had whooping-cough at 12 months, and "pneumonia" at 4; no other illnesses. At 5 he was admitted in April, 1906, to St. George's Hospital with fibrosis of the left upper lobe and bronchitis: while in hospital he showed irregular fever, 99°—101° every evening. In January, 1908, he was admitted to the Victoria Hospital with the complaint of cough and wasting: the signs of fibrosis Dr. JEX-BLAKE showed a case of "Fibrosis of the complaint of cough and wasting; the signs of fibrosis at the left apex were more marked, and there was slight clubbing of the finger tips. While in hospital he coughed little, and no sputum could be collected; the temperature was irregular, rising occasionally to 99°—100°.

On January 12th, 1909, he was brought to the hospital again, with a history of cough and general illness

for one week.

No sputum had been obtained since he had been in

hospital.

The X-ray examination shows general opacity of the upper part of the left lung; the heart is drawn over to the left; the diaphragm is low, and moves poorly on both sides. The chief point of interest about this case is that on admission it showed Grocco's para-vertebral triangle of dulness on the right side behind. The CHAIRMAN asked the opinion of members on the

value of Grocco's triangular dulness. He believed the sign to be present in this case, but some had said that it was present in every child, whether healthy or diseased.

Dr. EWART said that in his hands the Grocco sign had been valuable as a sign of fluid, but it was, of course, necessary to exclude the presence of dulness from consolidation. The crucial test was to change the position of the patient, and if the fluid was free the triangle of dulness should disappear, and should return on restoring the body to the former position. Empyemata, not being commonly free, did not answer to this test. When fluid filled the peritoneal cavity and raised the diaphragm, Grocco's sign could be found as a big equilateral triangle bisected by the

Dr. David Forsyth read a paper on

INFANT MORTALITY AS SEEN IN A CHILDREN'S HOSPITAL, a full abstract of which will be found in another column under the heading of "Original Papers."

In the discussion that followed.

The CHAIRMAN said the Section was much indebted to Dr. Forsyth. He commented on the few deaths attributed to rickets, due to the deaths from rickets being put under the heading of the terminal trouble, whatever it might be.

Dr. DUDFIELD said that Dr. Forsyth had shown a classification of deaths on a strictly scientific principle, which could not be said for the Registrar-General's classification. The Registrar-General's rule that if the duration of the disease was not mentioned on the death certificate, the first disease on the list should be taken as the cause of death, led to some curious results. For instance, syncope would be mentioned first and diabetes second. In a case of broncho-pneumonia or tubercle and whooping-cough, whooping-cough was usually selected for the cause of death. Marasmus was a very favourite term with the profession.

Dr. HUTCHISON expressed surprise that mastoid disease was responsible for 3 per cent. of the deaths. He did not think that this would be found to be the case at the Great Ormond Street Hospital. Might it be due to the large amount of whooping-cough treated at the Evelina?

Dr. Meredith Richards said that marasmic children admitted to hospital would have proper treatment, and many of them recover, whereas if they were not admitted to hospital death was more likely to occur. In tubercle also, there was a large amount of selection. Therefore it is necessary to take precautions when comparing hospital figures with those gleaned from the community in general.

Dr. W. EWART said that a post-morter, basis seemed to be the only reliable scientific one. The difference in statistics from a hospital and those from sources remote from hospitals was an index of the progress of medical science.

Dr. CAUTLEY congratulated Dr Forsyth on his energy in regard to the paper, but the conditions of hospital practice were so different from those in everyday life that he doubted the applicability of the results. He would have liked to have known the ages or the mean age of the cases.

Dr. FORSYTH, in reply, said that it was from the scientific aspect that he regarded the figures. The methods adopted in tabulating death registration were different from those in a hospital. He understood from Dr. Dudfield that if a child died from septic meningitis or mastoid disease twelve months after having suffered from scarlet fever, the death was attributed to scarlet fever. That was misleading. Another point was that his statistics were taken over a period of twenty-three years. Twenty-three years ago the deathrate from mastoid disease was probably much higher than now, and no doubt now it was less than 3 per cent. He had tried to show that a diagnosis on clinical data was not always a true one, post-mortem examinations giving the most accurate figures.

### ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

MEETING HELD FRIDAY, JANUARY 15TH, 1909.

The President, Dr. W. G. SMITH, in the Chair.

NOTES ON A YEAR'S MENTAL HOSPITAL WORK.

Dr. Dawson read a short report of the more interest.

DR. DAWSON read a short report of the more interesting points which had arisen in the practice of Farnham House Mental Hospital during the year ending March 31st, 1908. Of the admissions the essential cause in 29.4 per cent. was diathesis, in 47 per cent. various forms of moral and physical wear and tear, and in 23.5 per cent. toxic influences. There was, however, a neuropathic heredity in 71.4 per cent. The forms of disease in the cases due chiefly to diathesis were mania, melancholia, and dementia, with two cases of alcoholism. In one of the cases belonging to the second class the cause appeared to have been relief of anxiety. Of the toxic cases, one of alcoholic paranoia was quoted as showing that some alcoholic cases exhibit no symptoms pathognomonic of their origin. A case of true diabetic melancholia was also detailed, which recovered mentally when the sugar disappeared. Amongst the admissions melancholia had been the prevailing form of disease. As regards physical signs, albuminuria had been found in 12 cases, mostly of a depressed cast; glycosuria in 8. Arterial pressure was tested in 7 admissions, being found normal in 2, high in 5. A case was detailed which seemed to show that large doses of bromide may possibly lower resistance to micro-organisms. Thyroid treatment was tried in 7 cases, with good results in 3.

Two, however, were not improved, and the state of the heart induced by the drug had given some anxiety for a time. Atropin treatment had been used in 2 cases of alcoholism with some immediate success; unsuccessfully in a case of morphinism. Suprarenal had been found useful in keeping excitement in check. Some advantage had been found in the use of formates and lecithin.

The PRESIDENT said that, to the ordinary practitioner, the subject of ætiology, on which Dr. Dawson

had dwelt at the commencement of his paper, was, perhaps, the most important chapter in neurological If their minds were clear as to the circumstances that predisposed to insanity, the practitioner might sometimes be in a better position to forewarn patients, and be forearmed himself as to what to do.
The discussion in that Section last year had showed that the influence of alcoholism per se in the production of insanity had been over-rated. He was anxious to know if there were any definite mental variations correlated in any way with the forms of alcoholism. It was said that the police of France found absinthe drunkards to be homicidal, and had to separate them from the others, and it was possible that the essential oils in absinthe were important in producing pathological results. He would also like to know if there was any particular type of mind, or mental development, that was specially predisposed to alcoholic disturbance.

Dr. KIRKPATRICK thought that in two of the three groups of causation—diathesis and mental stress and strain—it was difficult to appreciate Dr. Dawson's exact meaning. He had some difficulty in understanding what he meant by regarding diathesis apart from heredity in some of his figures. Did he recognise a type of individual who was likely to go mad apart from any hereditary taint? He thought there was a difficulty in accepting mental stress and strain as a general cause of insanity, although it might be a predisposing cause in conjunction with some weakness, hereditary or acquired. It had been proved that eyestrain, either from want of muscle balance or errors of refraction, was capable of producing very serious nervous troubles, and many long-standing nervous diseases had been cured by correction of such errors, which might be a cause of trouble in the brain, and, under subsequent strain, might produce; insanity.

under subsequent strain, might produce insanity.

Dr. Dawson, in reply: The correlation of alcoholism and mental affection did not appear, as far as he was aware, to have been studied. He was strongly of opinion that anyone who had a neurotic heredity, or who had acquired it, should abstain absolutely from alcohol, as all such were liable to go to excess. Melancholic and demented patients were liable to suffer more from glycosuria than others. There were very few cases of insanity in which there were not contributory and exciting causes, and his classification was only intended to embrace what he considered the predominating cause of the particular attack. Diathesis was probably always hereditary, but it was not possible in all cases to trace the heredity. A widespread peculiarity, too trivial to excite any great remark, would produce a greater effect in the offspring than the occurrence in a family of a few sporadic attacks of insanity. He therefore held diathesis to be a different thing from heredity. He had not had experience of cases due to eye-strain.

INTRACRANIAL TUMOUR.

Dr. Drury read the history of a case of the above disease in a female, æt. 30. Her symptoms had lasted for six months before she came under observation. When seen, the cardinal symptoms of brain tumour were present, but there was nothing to indicate its position. As she was getting rapidly worse, unconsciousness impending, and sight almost gone, it was decided to ask Dr. Arthur Ball to do an operation for the relief of pressure. This was done on July 13th. A large trephine opening was made in the temporal region on the right side under the muscle; the dura opened, and a small quantity of fluid escaped; the wound then closed. Improvement followed rapidly; at intervals vomiting and headache returned, and the brain was tapped, fluid being drawn off on each occasion. These intervals became shorter, till eventually tapping had to be done daily. A tube was then inserted and kept in permanently for several weeks. During all this time very large quantities of fluid escaped. She improved so much that she could walk about, and could see and recognise people, and had nout, and could see and recognise people, and had about, and could see and recognise people, and had nouther headache nor vomiting. The wound was kept aseptic during the whole time. She suddenly became unconscious one morning and died the next morning, November 8th, nearly five months after operation. The case was brought forward to illustrate the merciful relief afforded by an operation of this kind, where

there were no symptoms to indicate the position of the lesion, and, therefore, where no operation with any hope of cure could be attempted. It was found that the lesion was a large cyst in the cerebellar and pontine regions, which could not have been dealt with even had it been localised.

NOTE ON POLIOMYELITIS OF THE CONUS MEDULLARIS. Dr. O'CARROLL read an account of a case of the above condition. A girl, æt. 17, had been sent up from the country suffering from "tumour of the bowel." This turned out to be a very big prolapse of the rectum. Some months previously she had had a febrile attack, following which she had suffered from incontinence of urine and fæces. Later the bowel prolapsed. The sphincter ani was entirely relaxed, and the opening of the urethra rather wide. Sensation was perfect. The the urethra rather wide. Sensation was perfect. The patient's general health was good. Under treatment, principally by the Faradic current, complete control was recovered in the rectum, but the patient was unable to retain urine for more than two hours when she left hospital.

#### OPHTHALMOLOGICAL SOCIETY UNITED KINGDOM. SOCIETY OF THE

MEETING HELD IN THE ROOMS OF THE MEDICAL SOCIETY OF LONDON, THURSDAY, JANUARY 28TH, 1909.

The President, Mr. R. MARCUS GUNN, in the Chair.

MR. A. W. ORMOND showed a case of tubercle of the choroid, and Mr. DOYNE a case showing peculiar opacities of the cornea.

Mr. BISHOP HARMAN read a paper on FOUR GENERATIONS OF LAMELLAR CATARACTS.

He showed the pedigree of a family for five generations, four of which presented a marked inheritance of congenital cataract. Seventeen childships were traced, comprising 63 persons; 8 died in infancy. Of the remaining 55, it was known that 19 had congenital cataract. In no case had there been any in-breeding or marriage with a person similarly affected. of cataract was, for the most part, central opacities of varying size; some were minute, Y, or X, or starshaped; others showed definite lamellar formation. In some cases the cataracts were of long standing, and no evidence could be found that they had progressed beyond the stage at which they were earlier seen. Probably the number of cases of cataract found did not represent the true total, for in one childship of seven members, amongst whom only one case of cataract was admitted, examination of the seven showed that four had lenticular opacities. The inheritance was strictly from those who had cataract; in no case was cataract found in a child where the parents were free from the defect. When a defect had disappeared from a branch of the family, it did not tend to reappear. The teeth usually were good, and no other developmental errors were found.

Mr. HARMAN also read notes of a case of unusually

RAPID DEVELOPMENT OF CATARACTS in a boy, æt. 9. A year previously his vision had been recorded at school as 6/18; an examination passed three months before showed that he could then write When seen he was quite blind; both lenses were completely cataractous; the lens matter was soft and opaque. The lenses were removed by curette evacua-tion at the Belgrave Hospital, and at the end of six weeks the boy left the hospital able to read 6/18 with cataract glasses, and later on he saw 6/6. He showed no trace of general disease, but there was some evidence

of defect in his ciliary vessels.

Mr. A. S. Percival (Newcastle) read a paper entitled NOTE ON THE COLOURS OF BENHAM'S TOP,

and he demonstrated the different colours shown when the top was rotated clockwise, as compared with those when the rotation was in the opposite direction. explanation, which was not yet certain, was highly technical, and he suggested several theories.

Mr. Percival also read a contribution on some RHYTHMIC OSCILLATIONS OF THE PUPIL.

He said that all were familiar with the rhythmic contraction and dilatation seen in certain diseases, and which were usually looked upon as of grave signifi-

cance. He compared this with the oscillatory discharge from a Leyden jar, which occurred under certain conditions. If it were discharged through a conductor of high resistance, the charge simply died away. If it were discharged through a good conductor, such as a coil of wire, the discharge consisted of a number of excessively rapid oscillations or surgings. He then compared the nerve cell and axis-cylinder with the Leyden jar and conducting wire, stating that, owing to disease, the discharge of nerve impulse was made in an irregular manner. He regarded the movement-tremors of disseminated sclerosis as an almost exact parallel to the oscillatory discharge of a Leyden jar.
Mr. David J. Wood (Cape Town) sent a communica-

tion on a case of

RETINAL EXUDATION WITH EXTREME DISTENSION OF

VESSELS, and perhaps arterio-venous anastomosis. He reminded members that he had contributed a similar case to the twelfth volume, and another to the twenty-fifth, and recently he had seen and examined a third instance of this rare condition. He saw the patient first in 1902, and ordered glasses for her; there was then no com-plaint of sight being bad. Later, as she had an attack of dimness of vision, he examined her fundi, and found large blood-vessels running up to a patch on the upper part of the fundus, which possibly might have resulted from a former hæmorrhage. The patient, who was then 50 years of age, returned in 1907, reporting that a few days previously the right eye had suddenly failed. He found that to be due to a diffuse opacity in the vitreous; no fundus details could be made out. Then the vitreous began to clear, and the drawing he showed presented a picture of the appearance. There was a white area above, and enormously dilated blood-vessels could be seen running up to it from the disc. The colour of the vessels, which were very tortuous, was intermediate between that of arteries and veins. From the left trunk a vessel sprang which was arterial in colour, while another vessel, obviously venous, sprang from the opposite main trunk. There were fine choroido-retinal changes, which covered the inner part of the fundus. thought the growth was probably surcomatous, and his colleague advised excision, but the author was so impressed with its likeness to his other cases that he held his hand. He hoped to report further on the case. He had not been able to hear more of his second case, already mentioned.

Mr. TREACHER COLLINS described a similar case, and remarked on the rarity of the condition; and Mr. G. COATS described the pathological findings in a case

he had thoroughly examined.

### CORRESPONDENCE.

### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

### FRANCE.

Paris, Jan. 31st, 1909.

LEPROSY IN FRANCE.

MANY persons live under the impression that leprosy belongs to another age and that it has disappeared from the surface of the earth for centuries. Such is not the case, unfortunately. It is to be met with in abundance in Europe, and more especially in Norway, where there are at present somewhat over 500 lepers treated in the hospitals or leprosaries: Bergen, Molde, and Trondhjen.

Russia possesses two important centres: the Baltic and Finland on the one hand, and the provinces shores of the Black Sea, the Caucasus, and the neighbourhood of the Caspian Sea on the other.

The Balkan peninsula is the most contaminated of the European regions, while 600 lepers may be counted at Constantinople, Greece, Montenegro mania also furnish a certain contingent. and Rou-

In Asia, the principal centre of leprosy is Hindustan, where there are over 130,000 lepers out of 200,000,000 inhabitants. A large number is also found in Central America.

In France there exists a popular belief that with the edict of Louis XIV. (August 24th, 1693) which suppressed leper hospitals in the country, all trace of the dire disease had disappeared.

The truth is that leprosy can be found in France under two forms: a typical and modified form.

According to Dr. Zambaco, who made a special study of the malady in its two characters, the modified form is very frequent in France, but passes under other names as new maladies: Morvain's disease, syringomyelia, sclero-dactylia, gangrene of the extremities, etc.

According to Professor Milian, the above form of leprosy can be met with not only in Brittany, but also along the shores of the Mediterranean.

THYROID INSUFFICIENCY. There are few problems in the domain of general physiology which have excited so much research and controversy as the rôle of the para-thyroidian apparatus, since Reverdin published several cases of myxœdema provoked by surgical extirpation of the gland.

As is well known, the apparatus is composed of the thyroid gland proper and four little glands; two external, situated on the posterior surface of the gland, and two internal included in the corresponding lobes. All these glands possess an internal secretion

as they are deprived of excreting canals.

The structure of thyroid gland differs from that of the satellites, and consequently they play a different rôle in the economy. Experimental research proves that the thyroid body regulates nutrition, while the small glands have principally to defend the economy against poisons elaborated by the organism.

It is needless to mention in detail the accidents resulting from the absence or atrophy of these organs, which in children result in cretinism, and in adults in obesity, somnolence, apathy, impaired memory and intelligence, dry, wrinkled skin, cyanosed extremities, low temperature, sensation of cold, etc.

But less known, perhaps, are the symptoms of insufficiency. Where this insufficiency is well marked, the diagnosis is easy, but when it is slight it is manifested by little signs which frequently pass unobserved. Drs. Rothschild and Levi have conjointly published a paper on this subject in which are enumerated all these signs that command attention.

Transitory Edema.—This cedema, white and indulent in character, but which has nothing in common with albuminuria, is found seated over the eyelids, the frontal region and the malar bones and anklus. It is generally intermittent and is provoked by fatigue, migraine, etc.

Eyebrow.—The external third of the eyebrow de-

prived of hair is very frequently seen in persons suffering from slight insufficiency, due to some trophic trouble or to a kind of keratosis of the piliary follicles (Hertoghe).

Sensation of Cold.—The thyroid body, having a thermogenic function, quite a series of disturbances in the calorification of the organism result from its derangement: cold extremities, sensation of dead finger, shivering running through the body, especially in the dorsal region, at certain moments of the day, between four and five o'clock in the evening; central temperature below the normal, predisposing to extreme sensitiveness to cold. The slightest draught provokes in these persons rheumatic pains, neuralgia,

lumbago, migraines, coryza, tonsillitis, etc.

Fatigue.—Patients of the above type complain
easily of lassitude, and, as remarked Hertoghe, this
feeling of weariness is frequently observed in the morning.

Headache.—Cephalalgia is more intense in the morning, but disappears towards the afternoon after a good repast. The patients are so accustomed to this continual headache that they hardly speak of it.

Obssity.—Thyroid insufficiency is frequently accompanied by embon point, if not absolute obesity, constituting, according to Mr. Hubierge, a modified form of myxædema. In women, the menses are observed to be too frequent, too abundant, or too prolonged. Such are the symptoms observed in adults. In chil-

dren where the thyroid insufficiency is well marked, the mental and physical conditions are very backward, while nanism, cretinism, myxædema are the rule. Where the insufficiency is slight, the patients are undeveloped, the intellect somewhat obscured, and puberty retarded. The rational treatment of all these conditions is that by thyroid extracts, of which there are several preparations in the market.

GERMANY.

Berlin, Jan. 31st, 1909. AT the Verein für Innere Medizin, Hr. Ludwig Meyer introduced a discussion with a paper on

EXPERIMENTAL INVESTIGATIONS INTO ALIMENTARY FEVER.

He remarked, by way of introduction, that it was recognised that large doses of common salt introduced into the alimentary canal acted as a poison, both in animals and the human subject. With sufficiently large doses death took place in a few hours by means of purely physical processes. Many symptoms coming on after such large doses had been described, but the heightened body temperature caused by it had only lately come under observation in the city Kinder-

The speaker approached three questions experimentally: (1) In what degree of concentration does salt act pyretogenically? (2) What are the behaviours of healthy and unhealthy infants in regard to such concentration? (3) Is the pyretogenic action the pro-

Young infants were given 100 grm. of a correspondingly dosed solution twice, the periods separated by intervals of two hours. General disturbances were never observed. At first strong concentrations of saline solution were tried. Concentrations of salt of 3 to 100, in 11 cases, mostly healthy infants, always caused fever, in part the temperature remained subfebrile, in part high fever was produced (39 and 40° C.).

The course of the heightened temperature was always the same: Rise after 2 hours, the acme after 6 hours, the fall to normal after 12 to 24 hours. The speaker spoke of the fever—after excluding bacterial and inflammatory causes—as directly or indirectly due to the salt.

Reduction of the concentration to the physiological degree (0.75) in doses of 100 grm., never caused alteration of the body heat either in infants suffering from alimentary disturbances, or in healthy ones. A considerable increase of the quantity given caused a rise of temperature in infants suffering from disturbances of nutrition, but not in healthy ones. These differences between healthy infants were more marked when stronger solutions were made use of (1 per cent.). With this those infants, almost exclusively, that were suffering from acute intestinal disturbances, reacted with a rise of temperature. An important part must therefore, be attributed to the intestinal walls and to the intestinal epithelium in cases of poisoning with hypertonic solutions of salt. If this pyretogenic action of salt solutions was due solely to processes of a physico-chemical nature, solutions of other salts which were iso-osmotic with 1 per cent. solutions of common salt must set up a similar effect. That was not the case, however, a 3 per cent. solution of potassic iodide did not alter the temperature at all.

The pyretogenic action was therefore a specific one; which part of molecules of ClNa was the carrier must be analysed. Other iso-osmotic combinations (KCl) were also without any influence on the temperature, and other Kations K and Ca combinations, KBrm, KPHO<sub>4</sub>, CaCl<sub>2</sub>, had just as little power of raising the temperature.

The fever action was, therefore, exclusively associated with the Kation Na. But not all the Na combinations produced similar effects. The speaker divided them into apyretogenic and pyretogenic groups. The speaker To the first belonged sod. sulph., sod. lact., sod. acet., sod. salicyl., sod. bicarb., and to the latter sod. brom., sod, iodat., and this caused a rise of temperature exactly similar to that caused by the sodium chloride.

In looking over the histories of cases of poisoning by salt, and making a comparison with the cases produced experimentally, he was inclined to the opinion that the poisoning was due to the rapid absorption of these particular combinations.

Hr. Rosenheim was moved by the address to think of the idiosyncrasies not unfrequently met with as cases of fever set up by food. He recalled a case of the kind, that of a girl of 12, who suffered from fever for 15 months—sometimes very high—in connection with acute indigestion. All treatment was powerless, and the little patient became much prostrated. By a radical change of diet the fever was removed in two days. She had been given a diet in which eggs and meat juices played a considerable part, and these were now left out. Some time afterwards they were again introduced and the fever returned in a severe form. He had seen three similar cases; two of the patients were women who had had influenza with diarrhœa. Although improvement took place, the patients felt very weak and the temperature rose in the evening. In these cases the high temperature remained even when the diet was changed. The third case was that of the son of a medical friend. The boy became very feverish from an error of diet; the intestinal catarrh improved, but the fever persisted, so that he was sent to a hydropathic establishment, where improvement took place. Afterwards, however, fever came on regularly in the evening, against which no change of diet was of service. This condition had lasted 21 months when the speaker first saw the patient. Here, also, a radical change of diet caused a striking change of condition. No bacteria were found in the stools.

Hr. Brugsch remarked that the intravenous injection

of salt set up fever.

Hr. Albu looked on salt fever as a kind of autointoxication. The intestinal epithelium was not sufficiently active. There were cases in practice where the fever could not be traced to any error of diet, but was simply due to intoxication from imperfect action of the intestines. Alimentary fever was of local origin.

### AUSTRIA.

:Vienna, Jan. 31st, 1909.

MORPHIA POISONING.

At the Gesellschaft, Lehndorff recorded the case of a child, 7 weeks old, that suffered from morphinism, induced by using a suppository. The child became cyanotic; temperature, 33° C., or 92° F., with slow pulse and respiration. The pupils were like pinheads, reflex greatly exalted, while the child had all the appearance of larynx stenosis, which was relieved by intubation.

Knopfelmacher said that he had recently met with a similar case of poisoning, with cramps and laryngeal spasm. He also observed that this poisoning was not uncommon with codeia, as well as tincture of opium. Such cases can only be treated with expectants, as recovery is always doubtful. At this stage Knopfelmacher showed a case of chronic congenital hydrocephalus. The cranium measured 68 ctms., and the reflex was greatly exalted. He had performed 88 lumbar punctures, which seemed to inhibit the increase of the hydrocephalus.

CHRONIC TETANY.

Escherich showed a child, 13 months old, who, since the third month, had typical tetanic contractions associated with the facial phenomena and excited with the electric stimuli. There was no rachitis present, and Escherich attributed the disease to the insufficiency of the epithelium bodies in the thyroid. With this object in view, his therapeutic treatment was directed to implementation of more epithelial bodies in the gland, which we hope to hear more of in the future.

Fleishmann gave a brief account of his experiments in congenital tetany, attributed to hypoplasia of the enamel of the teeth. He had met with seven cases where chronic tetany was present, associated with hypoplasia of the enamel, which probably depended primarily on the insufficiency of the epithelial bodies.

the insufficiency of the epithelial bodies.

Erdheim had found that the same condition produced a stunting of the growth of the teeth, as well

as ectoderma of the body. One particular condition in connection with tetany may be mentioned, that it mostly appears in the second half-year of life. Neurath remarked that ectodermal formations were not confired to tetany as they appeared in other diseases where development was disturbed; for example, in typhus the hair fell out; in scarlet fever the nails became ribbed, etc.

ACUTE BULBAR PARALYSIS.

Popper presented a boy, æt. 6, with acute bulbar paralysis, which had for its origin poliomyelitis. At one time the paralysis seemed to recede, and the cerebral ataxia as well as the nystagmus improved. Hitherto the unsteady gait, weakness of the facialis, and paralysis of the ocular muscles were absent, as well as the paralysis of the extremities.

Tuberculosis as an Infantile Disease. Hamburger read a paper on tuberculosis as a disease of childhood, although he held that puberty and advancing years see an outbreak of the latent centres in the form of pulmonary phthisis, which is only another manifestation of a latent centre of tubercle. The exacerbation is only a removal of the infection from the old centre to some new point, and hence it becomes auto-infectious. It is one of the peculiarities of phthisis that tuberculosis flourishes best in a tubercular organism, and thus phthisis is always seen as a late form of tubercle. According to anatomical results, the so-called recent tuberculosis of the adult is therefore not a correct description of the form of infection, but is more likely to be implanted in the infant, which is the most important question of the day.

### FROM OUR SPECIAL CORRESPONDENTS AT HOME.

### BELFAST

NOTIFICATION OF BIRTHS ACT.—The first prosecution under this Act in Belfast took place last week, when a midwife who attended a woman in her confinement, and the husband of the woman, were summoned for neglect to notify. The Medical Officer of Health said that the failures to notify births were no less than 30 per cent., and the authorities were determined to prosecute. All medical men in the city had been informed by circular of the coming into force of the Act, but it was impossible so to warn midwives, as they were not registered in Ireland. The midwives had been personally warned, and the midwife who was summoned had been warned three times. It was only through the death of the child that this case came to their notice. The father was discharged, and the midwife was fined 5s. and costs.

NEWTOWNARDS NURSING SOCIETY: ADDRESS BY PROFESSOR LINDSAY.—The sixteenth annual meeting of the Newtownards Nursing Society was held last week, when the Marchioness of Londonderry presided. Professor Lindsay was present, and gave an address on "The Necessary Conditions of a Healthy Community." He laid down ten conditions as essential for a healthy community, as follows:—(1) A suitable site for the town; (2) a stock of average soundness and vigour; (3) healthy houses; (4) a pure and adequate water supply; (5) a suitable food supply; (6) proper sanitation, domestic and urban; (7) the regulation of trades and employments; (8) proper school buildings, and the medical inspection of schools and scholars; (9) temperance; (10) suitable arrangements for the care of the sick, and for the isolation of infectious disease. Professor Lindsay emphasised the point that at least one-quarter of all disease was preventable, and that prevention is not only cheaper, but better than cure.

BELFAST HOSPITAL FOR SICK CHILDREN.—The annual meeting of this hospital was held last week, Bishop Crozier presiding, and moved the adoption of the report. This was seconded by Mr. John Stevenson, Chairman of the Ulster Hospital for Children and Women, who referred to the friendly feeling between the two hospitals and the abundant scope for both on the two sides of the river. The medical staff report was read by Mr. T. S. Kirk. It recorded that the

intern patients numbered 666, the surgical operations 375, and the total attendances at the extern 12,069. Allusion was made in feeling terms to the great loss sustained by the hospital in the death last year of Dr.

Sidney Smyth.

FORSTER GREEN HOSPITAL.—The annual meeting of this hospital was held in Belfast last week, Mr. Herbert Ewart presiding. The work of the hospital was seriously interrupted for several months last year, the hospital being closed for building operations, new wards being added to accommodate the patients who are now sent to the hospital by the Public Health authorities under a special agreement. The new building accommodates 73 patients, and will admit of considerable enlargement if needed. Dr. Thos. Houston read the report of the medical staff, which recorded the treatment of 167 patients in the wards, and 425 new cases in the extern department during the year. Professor Lindsay, who spoke, said that it had been cal-culated that there ought to be one bed for the treatment of tuberculosis for every thousand of the population, which would mean about 4,500 beds for Ireland. There were only about a tenth of this, but, of these, two-thirds were at or near Belfast. Since Ireland two-thirds were at or near Belfast. suffered so much, he thought 4,500 beds was the minimum required, and such could not be provided by charity alone. He referred to the assistance given by the great insurance companies in Germany, who found it paid them to provide treatment in sanatoria for those insured with them.

### LETTERS TO THE EDITOR.

HE EXCLUSION OF IRISH AND SCOTCH DIPLOMATES FROM ENGLISH HOSPITALS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Touching on the question of the exclusion of the holders of Scotch and Irish qualifications from most of the important London and many of the provincial hospital appointments, I am quite of the opinion that it would be well to obliterate those clauses —in the rules which govern the elections to the staffs of hospitals—which have any reference to the diplomas to be held by candidates for such appointments.

I think the obliteration of such clauses would be distinctly, though, perhaps, rarely, in favour of the hospitals, for if no such clauses existed there would be from time to time a candidate elected who does not happen to hold either the diploma of the London College of Surgeons or of the London College of Physicians; but I think there is very little doubt that that candidate would be the best among those applying for the appointment, and that the election would be certainly on the merits of the individual-in fact, the candidate elected would be the man whom the governing body of the hospital would desire to have on their staff, to the exclusion of all the other candidates, notwithstanding the fact that they might hold the diplomas of the London Colleges.

On the other hand, if the clauses referred to were removed, there would be no compulsion on the part of the hospital governing body to elect the candidate who might be Scotch or Irish, and they certainly would not do so unless his greater merits outweighed the merits, plus the possible greater acquaintance and knowledge of the character of one or more of the candidates who might hold the diplomas of the London Colleges.

Therefore, I say that it would be advantageous to the candidates, and also to the hospitals, that these clauses should be removed At the same time, I would urgo that the professional brotherly feeling which would be exhibited by the removal of these clauses should be reciprocated all round—that is, in Scotland

and in Ireland.

Scotch and Irish members of the profession practising in London and the provinces are certainly received by the profession in England absolutely without any distinction. Is it quite the same when vice versa? Can we not recall the time when it was proposed that an English examiner should be associated with . . . examiner at a certain . . . University?
The local journals were outraged, and declared that such an election would be a slur upon the nation. Do we not find other forms of cliqueism where such should not exist? It may be called patriotism, but patriotism which does not extend to the Empire is false, selfish, and degrading.

I am, Sir, yours truly,
A. T. NORTON, C.B., F.R.C.S.

### ANTI-VIVISECTION FANATICISM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,-Publication in the Times of the circular issued by an amiable anti-vivisectionist, calling upon supporters of the cause to pray to a merciful God for the "removal" of leading physiologists, and suggesting that prayer had already led to the "dropping" of one eminent man, has been followed by the usual correspondence. The Hon. Mr. Stephen Coleridge is, of course, to the fore. Mr. Coleridge has long ceased to afford pure amusement; he now excites little else than pity. From his point of view he has mastered the vivisection question; from our point of view it has mastered him. In this condition of obsession he is evidently quite unconscious of the unintentional tone of malignancy and hatred which seems to be conveyed through his writings. He, and those of his followers in a similar state of mind, must endure constant misery through contemplation of the horrors of the physiologist's laboratory which are ever present to their imaginations; they are all objects for commiseration. Mr. Bernard Shaw shows, at any rate, by his share in the discussion, that he has not yet quite earned the right to the title of "the British Tolstoy," which, I am told, has been bestowed upon him by some of his followers. His contribution to the Times consists of a brief yet ponderous and laboured joke, quite up to the level one might expect in a "littery gent," but far from good enough to carry the signature of a philosophical, wise, and magnanimous man of letters. These leading anti-vivisectionists and their fellows, luckily, have so far failed to hamper in the least the progress of research in these islands, and as there seems less prospect than ever of their being able to accomplish anything, physiologists can look upon their performances with complacency. If anything were needed to complete the hopelessness of their cause, it might be found in the effusions of paid officers of their societies, which on every occasion are in evidence. Some of these gentlemen are gaining good incomes from their offices. Unless human nature for once has changed, the last thing they can really hope for is the success of the movement for which they are ostensibly working. Once vivisection is put a stop to, their profitable occupation would be gone. Hence, no doubt, the delight of some of them at rushing into print on every opportunity, while cherishing a shrewd suspicion that they are thus helping to postpone the day when the aspirations of their generous paymasters shall be realised.

I am, Sir, yours truly, A SURREY DOCTOR.

Near Reigate, January 27th, 1909.

### INCONTINENCE OF URINE ASSOCIATED WITH EPISPADIAS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The communication by Mr. R. P. Rowlands you publish in THE MEDICAL PRESS AND CIRCULAR of anuary 27th, under the above heading, is most interesting. I am quite in accord with the author that the method employed is original, especially with reference to all the work being external to the mucous membrane, which is not injured. The most important points I consider are—(1) The proof that the nervous supply was sufficient to give control after the small amount of muscular tissue at the neck of the bladder had been joined over the urethra; (2) the ease with which the pubic bodies could be retracted in a boy as old as 6 years, without any interference with the sacroiliac synchondroses. May I ask Mr. Rowlands if he experienced much difficulty in separating the neck of the bladder and the short urethra from the pubic bones, and also from their lateral attachments? I would also like to know if there was any trouble in

re-introducing the catheter after its removal on the fourth day; this evidently must have necessitated the employment of great care in order to avoid disturb-ing the structures which had been joined over the urethra and which, as Mr. Rowlands says, firmly gripped the instrument after the operation. I am certain that all surgeons would be anxious to see in THE MEDICAL PRESS AND CIRCULAR an account of any subsequent operation Mr. Rowlands may undertake on this patient for the correction of the epispadias.

I am, Sir, yours truly,
A LONDON SURGEON

ONE MORE CAUSE OF THE SPREAD OF CONSUMPTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,-Few people think, when they lay their heads upon a pillow to take their night's rest, of the danger they run of infection from a pillow which they themselves or others may have rendered by their breath a hot-bed of disease. Of all bedding or bed clothing, none is more liable to do mischief than a pillow, for, beyond the changing of pillow-cases more or less frequently, nothing further is done to lessen the power for ill of the swarms of germs constantly and steadily breathed into the pillow through the night, and it is only due to the power of individual resistance that disease is not more rapidly spread. The power of resisting the invasion of germs being less at night, and the head being in close contact with the pillow, may account for the persistence of many respiratory diseases. Can, therefore, any of your readers suggest an apparatus, simple of construction and easy of use, and sufficiently cheap to be within the reach of the masses, yet capable of effectually sterilising pillows?

I am, Sir, yours truly, ROBT. HUGH HODGSON, M.D.

Peckham, January 27th, 1909.

THE TIMES AND QUACK ADVERTISEMENTS. To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the letter which you do me the honour to print to-day, January 27th, I pointed out that many inebriates owe their fall "to trust in one or other of the sham tonics containing alcohol, now so enormously advertised." The Times, in a leader, also, to-day, on "The Care of the Inebriate," expresses more strongly the same opinion in the following passage:-

"Every inebriate, however, passes through an early or preliminary stage; and the time-honoured principle, to oppose beginnings, might in very many cases be applied to him successfully if we would only look facts in the face, and endeavour to educate the public opinion by which, in the opinion of the committee, the Legislature has twice been deterred from accepting the good advice offered for its guidance. In the case of drugs, much might be done by a more strict interpretation and enforcement of the laws against the sale of poisons, and by the absolute prohibition of the many quack medicines, advertised as remedies for various complaints, which owe their popularity to the cocaine, the morphia, or the alcohol which they contain, and to the temporary and delusive sense of comfort which they afford. Preparations of this class are the frequent causes of an ultimate resort to the same agents in

stronger forms; just as the practice of taking irregular drinks at all periods for so-called good-fellowship, or for 'any other reason why,' is a common precursor of habitual intoxication." This affords one more illustration of the fact to which you referred in a recent editorial-namely, that,

in the matter of medical quackery throughout, it is evident that the editor of the *Times* does not know what the manager is doing, and the manager is not cognisant of what the editor is writing. The editor on occasion denounces various systems of quackery, the advertisements of which are freely admitted to his own paper. Surely, if "absolute prohibition" by law of certain advertised quack medicines is called for, the advertisements of these pernicious preparations ought not to be admitted to respectable newspapers. If the editor of the *Times* will look through a recent file of his paper, he may

easily discover plenty of advertisements of this class. If a column of the *Times* costs, as I believe, £20, the size of these advertisements forms a measure both of the total outlay and of the enormous extent to which alcohol, under the mask of sham, harmless tonics is being consumed by the innocent and ignorant public. The appearance of quack advertisements in a paper which denounces quackery must surely help to deceive the ingenuous reader, and make him believe that these announcements at least are to be relied upon. I ask with you, Sir, is it possible the proprietors of the *Times* are aware of what is being done in these matters with their great paper? Is it possible that, if aware of these facts, they could allow the infliction of damage to the prestige of the *Times*, which must surely outweigh by far the money gain derived from such an abuse of their advertising columns.

I am, Sir, yours truly, MEDICAL TEMPERANCE REFORMER.

January 29th, 1909.

THE LATE JOHN HOLDEN WEBB, M.R.C.S.Eng., L.R.C.P.LOND., OF MELBOURNE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,-To no one more than myself has the news of the death of Mr. J. H. Webb caused more sincere regret and sorrow.

On many occasions I have drawn attention to his original work (a) with further views on the subject of cancer, received from him in correspondence, and published by me in accordance with his wish; and you, Sir, have been good enough, during the last four years, from time to time to publish these communications in some conjunction with my own.

In addition to the points in Webb's professional career noted in The Medical Press and Circular of January 27th, I think I am right in saying that formerly he was Assistant Surgeon in the Army Medical Department, and at the time of his death was Consulting Surgeon to the Melbourne Hospital. After settling in Melbourne, he rapidly acquired a reputation and enjoyed an extensive practice as a surgeon. With others, however, he suffered losses in the financial troubles in Australia some years ago.

During the last fifteen years he devoted himself to the subject of cancer, and though a surgeon himself, he was drawn to the clinical and medical side of the

In this respect, while recognising cancer as a local disease, in some cases due to causes having a purely local action and cured by operation, for the most part he regarded cancer as a general disease, due to central or intrinsic causes. Unable to define the boundary, in both forms he held that cancer is cell proliferation, due to the loss of some secretion, and in his opinion the crystallisation of cholesterin from the living cell, either locally from injury or de-pendent on some chemical change in the liver secretion, associated with deficiency of the bile salts or soaps, which normally hold cholesterin in solution.

Whether the theory was exactly right was a matter

of opinion, as he often wrote, but he was convinced himself of the influence for good in cases of inoperable cancer by his method of treatment by sodium oleate injections and purified ox gall by the mouth, and illustrated in various published cases, with independent confirmation. Even in regard to this treatment of his, he in no way asserted that he had reached finality. He thought it was on right lines, and capable of improvement.

I never met Webb, but his letters and his work appealed to me in their initiative and evident sincerity. Discouraged often by the lack of appreciation of his efforts and want of opportunity he experienced, there was nothing bitter in his letters, or petty about Webb. While holding to his views, he was willing to generously acknowledge the work of others or incorporate it with his own.

I was on the point of writing to assure him that

(a) The Lance', Oct. 12, 1901.

the subject of cholesterin in cancer, though still in a state of evolution at the present time, independently is receiving attention at home and abroad, and it is sad to think that Webb has not lived to find the recognition of his work which is his due. Pneumonia was the beginning of his illness, followed by heart and kidney complications. His death, at the age of 62, removes one whose name will be gratefully remembered by many who knew him and by those, like myself, who appreciated his work.

I am, Sir, yours truly,
J. A. SHAW-MACKENZIE.

Jan. 30th, 1909.

### **OBITUARY.**

WASHINGTON L. WINTERBOTHAM, M.B.LOND.,

J.P., V.D. WE regret to announce the death of Dr. W. L. Winterbotham, J.P., a gentleman who had been connected with Bridgwater for a large number of years. Dr. Winterbotham, who was about 70 years of age, had been in failing health for several years, but his death came about somewhat unexpectedly. He had been one of the leading medical practitioners in the town and neighbourhood, but since being joined by a partner several years ago, he had not actively pura partner several years ago, he had not actively pur-sued his profession. He was also well known, espe-cially years ago, as an ardent politician, and pos-sessing great powers of oratory, he ably championed the cause of Liberalism. At the time of his death he held the position of Chairman of the Bridgwater Divisional Liberal Association. He was one of the first county councillors of the borough, though he only held the position for one term of office, and he was also, some years ago, a member of the Town Council. He took great interest in the local hospital, of which he was Honorary Consulting Surgeon, and for many years had been a justice of the peace for the county. With the Somerset Archæological Society he had for years been closely identified, and that Society, by his death, has lost a most valuable member.

DR. GEORGE ELLIS.

THE death of one, who must have been the doyen of the medical profession in Ireland, occurred last week when Dr. George Ellis passed away in his hundredth year. Dr. Ellis, who lived at 91 Upper Leeson Street, had retired from active practice for some forty years, being a man of private means. He was a Fellow of the Royal College of Surgeons, and perhaps he had devoted himself more to the scientific than the active side of his profession. Dr. Ellis graduated at Trinity College in the year 1831, and received the degree of M.B. in 1834. In 1852 he published a work entitled "Irish Ethnology, Socially and Politically Considered." He was the vivor of three nonagenarian medical men, all of whom have now passed away. The two others were Sir John Banks, K.C.B., and Dr. Henry Tweedy.

### REVIEWS OF BOOKS.

AND CAMMIDGE ON THE PANCREAS. (a) MAYO ROBSON

This book shows careful study of the voluminous literature of the subject in every European language, the authors having taken great pains to collect informa-tion for the use of the English reader. Though full Though full of instruction for those willing to read a big work on the pancreas, the monograph might with advantage have been made less bulky by omitting a large number of debatable points and avoiding a like number of repetitions. The price at which it is published is

(a) "The Pancreas: Its Surgery and Pathology." By A. W. Mayo Robson, D.So.Leeds, F.R.C.S. Eng., and J. P. Cammidge, M.B.Lond., D.P.H.Camb, With numerous illustrations, London and Philadelphia: W. B. Saunders and Co. Price 21s. net.

somewhat prohibitive, seeing that it belongs to the class of books likely soon to be replaced by a new edition. The authors themselves candidly admit "that there are, as yet, many points on which observers are not agreed, and there are questions which still call for elucidation," and go on to say that "we do not consider that at present we are in a position to make more positive statements than those expressed in the chapter on chemical pathology, but we hope that we may shortly be able to do so." It being now recognised that the pancreas, instead of being a mere accessory organ of digestion, is greatly concerned in the maintenance of the health of the individual, clinicians will profit by a perusal of Messrs. Mayo Robson and Cammidge's elaborate work. Even the busy practitioner may well renew his knowledge of the anatomy, physiology, and pathology of the pancreas by glancing through the first 188 pages.

The chapter on chemical pathology may be reckoned as the main portion of the book, and proves laborious effort on the part of both authors. From their own observations on the fat contents of the fæces in disease of the pancreas they are able to confirm that in advanced pancreatic disease the stools have very typical characteristics-frequency, softness, bulk and whiteness, the last being due to the presence of neutral fats. In their opinion steatorrhœa is an unmistakable indication of pancreatitis, although, on page 327, they go on to state that in some cases of undoubted disease of the pancreas that came under their own personal observation the stools did not contain an excess of fats, and where an excess was present the relation between "neutral fats" and combined "fatty acids" was not markedly disturbed or there was excess of the latter contrary to what should be expected. The reasons they give for the absence of the excess of fat are:—

(1) Ingestion of food containing an abnormally small quantity of fatty material, owing to distaste for

(2) A diet containing fats which are readily digested and easily absorbed, e.g., a milk diet.

(3) Action of fat-splitting ferment in the stomach. The high proportion of combined fatty acids is accounted for by:-

 Bacterial action in the intestines.
 The examination being made in the early stages of the disease, before the pancreatic juice is diminished, or when actually increased.

(3) Enteritis hurrying the contents of the intestines onwards to the large bowel before being absorbed.

In spite of a good deal of original observation, and their "improved method" of examination of urine, they do not consider the presence of a pentose in that excretion as being dependent upon disease of the pancreas. They maintain that a positive reaction by the improved method of performing the so-called "pancreatic reaction" is suggestive of inflammatory disease of the pancreas, but they are not prepared to contend that it is pathognomonic of pancreatitis. We agree in their advice that in every suspected case of disease involving the pancreas the stools and urine should be subjected to examination by an experienced clinical pathologist, as his interpretation may, in the majority of cases, help to "clinch the diagnosis." The authors have taken great trouble to emphasise the importance of taking into account the examination of the urine and fæces, as well as clinical symptoms, before diagnosing disease connected with the pancreas. The referto cases in which pancreatic disease has been mistaken for sprue and malaria are interesting. pancreatic origin of diabetes is well sketched in the chapter devoted to it, and, in spite of the conflicting views held by the profession, both at home and abroad, the authors furnish instructive reading on the subject. They hold that glycosuria is not common in pencreatic disease, and when sugar is found in the urine it generally occurs in the form of dextrose—maltose rarely—pentosuria being very exceptional. The authors' classification of inflammatory diseases of the pancreas is the generally accepted one, though perhaps without the sub-division, under acute, in group B. We differ from them when they speak of ultra-acute, but that is only a matter of opinion. Thirty-four pages are devoted to general symptomatology and diagnosis; a good deal of what had been said of fæces and urine is repeated here. This portion of the book is a careful survey of the symptoms and physical signs met with in the disease, and may be commended to the attention of those who so firmly hold the idea that disease of the pancreas is unrecognisable during life. The histories of cases given in this chapter, and in the remainder of the work, are worthy of careful perusal. The diagrams are deserving of praise, especially those reproduced from Testut.

TREATMENT OF INTERNAL DISEASES. (a)
HERE we have a portly volume of upwards of 600
pages exclusively devoted to treatment—it positively
makes the pulse beat more quickly in joyful anticipation of a therapeutical feast. The pages teem with
prescriptions, couched in approved dog-Latin; we are
not even left in doubt as to terminations—often a
bugbear to the prescriber.

Three hands, or rather heads, have contributed to the English, or, shall we say, American version of the gospel of therapeutics. Dr. Ortner has his say, then the translator renders it into English, whereupon the Editor trips in between brackets, in a nagging sort of way, and handles the author's statements quite unceremoniously, often, indeed, flatly contradicting them. The effect on the reader is a trifle disconcerting, because he cannot help sympathising with the author, who is not there to defend himself. It is only fair to add, however, that Dr. Potter's interjections are characterised by sound common-sense, and his modifications and suggestions will probably commend themselves for Were it not for some of his additions, adoption. indeed, the volume would in many respects not be up-to-date." Merely to take the treatment of hæmoptysis, by way of example, the author prescribes ergot, hamamelis, and the whole series of reputed astringents in the old-fashioned way, apparently in blissful ignorance of the fact that, though still prescribed, they are hopelessly discredited. Fortunately, Dr. Potter is there to recall the fact, however discreetly, that remedies which lower the blood pressure are vastly more effectual in arresting hæmorrhage than those that tend to raise it. The same remark applies to the hypodermic exhibition of quinine in severe cases of malaria, for which we are indebted to the Editor.

There are many good features about the book, redolent of the pharmacy though it be. The author is particularly good on diet and regimen, and his instructions are characterised by detail and thoroughness, and for this reason cannot fail to be appreciated by the practitioner who is sick of vague general directions and sighs for something concrete, lists of articles of food and their quantities, schemes for the day's meals, and the various ways of preparing the appropriate substances.

It strikes us as somewhat remarkable that it should have been thought necessary to adapt a German book on therapeutics as though the task of compilation—for that is all it amounts to—could not have been done as efficiently by an Anglo-Saxon author off his own bat. By whomsoever written, it constitutes a very handy and resourceful work of reference, from which every practitioner may derive useful practical information.

### CLIMATE IN RELATION TO MAN. (b)

A WORK on climate ought to possess considerable interest for the general reader, inasmuch as climate is in reality an aggregate term for weather, and weather is a never-failing topic of conversation. We fear, however, that even in a work "which can be read by an intelligent person who has not had special or extended training in the technicalities of the science," as this one professes to be, the science will only appeal to those who have technical reasons for consulting its

pages. The earlier chapters are devoted to a classification of climates and a description of the zones within which each kind of climate is met with. Here we learn what constitutes a temperate climate (which may roughly be described as eminently changeable and uncertain), and we are taught the peculiarities of the extreme climates. The next step is to explain, as far as may be, how these climatic conditions are brought about.

To medical readers the chief interest of this compilation will be found in the chapter on the "hygiene of the zones." In it we have general considerations on the relations of climate and health which, as the author aptly remarks, is a very complex subject for the study of the causal connection between atmospheric conditions and disease, and has led observers to very contradictory conclusions. No doubt much of the confusion is due to the pernicious practice of generalising on insufficient data. Then, too, there are so many circumstances and conditions, independent of climate, that influence the incidence of disease, so that only the widest, not to say vaguest, conclusions are permissible.

The death-rates that obtain in this or that zone afford but a partial and imperfect idea of the morbidity of such zones, yet these rates constitute practically the only certain statistical data available.

Incidentally, we learn something concerning diseases peculiar to certain climates, their mode of propagation and the means of avoiding them, and this information will, doubtless, appeal more to non-medical readers anxious to cultivate the "intelligent adaptation of the physiology of the individual" which makes for acclimatisation.

The book contains much interesting information on habits of life under various climatic conditions and on the adaptability of the human organism to extremes.

### AN ALABAMA STUDENT. (a)

This volume of biographical essays is a collection of addresses already published in various medical The opening essay from which the book journals. derives its title deals with the life story of a certain Dr. John Bassett, who lived in the first half of last century. This man, devoted to medical science, left his native shores and visited France, and also this country in pursuit of learning. The extracts from his letters which Professor Osler gives are of great interest. They tell of a man of originality of mind and purpose, not one of the common herd, content to go on in the same hum-drum mode of existence as his fellows. He died in 1851 of tuberculosis. In a letter written to a friend in the spring of that year, he says: "This world has never occupied a very large share of my attention or love. I have asked but little of it, and got but little of what I asked." What was true of Bassett, is true of many medical martyrs of our own time. Many a worker is doomed to remain unknown to fame because of jealousies and misunderstandings, alas! too common in the medical profession. Many a man if he had his due would to-day be at the top, while some who, from private wealth or other causes, would be destined to take a back seat, so to speak, in the world of medicine. Some of the other notable characters considered are Thomas Dover, John Keats, Oliver Wendell Holmes, John Locke, William Pepper, and Sir Thomas Browne. The concluding essay is on Harvey, being the Harveian Oration delivered before the London College of Physicians in 1906. The lives of great men in our profession must ever stimulate us to fresh endeavours to follow in their footsteps. Centuries may have come and gone since they lived and worked, but medicine is medicine still. Our patients are the same frail creatures of a day; and if we can but catch the spirit and somewhat of the influence left by the great ones whose names are here recorded, we shall, indeed, owe a debt of gratitude to Professor Osler for issuing these essays in this handy form.

#### News in Brief. MEDICAL

#### Research Defence Association—Dublin B anch.

A MEETING organised for the purpose of forming a Dublin Branch of the Research Defence Society was held last week in the Theatre of the Royal Dublin Society, Leinster House. Sir John G. Nutting, Bart., D.L., presided. The meeting was very numerously attended.

The Chairman, in opening the proceedings, said that he took the chair in the unavoidable absence of the Earl of Cromer. The fact that in Dublin, before the branch had actually been formed, 200 persons of every class and profession, in addition to the medical men, had announced their intention of joining the proposed branch, showed that there was a widespread feeling in Ireland in favour of scientific research. The formation of the proposed branch was undertaken for the purpose of dispelling misapprehensions on the subject.

The Very Rev. the Dean of St. Patrick's proposed:—

"That a Dublin Branch of the Research Defence Society be, and is hereby, established." In doing so, Dean Bernard said that he felt honoured by the confidence which had entrusted him with proposing that resolution. But, at the same time, he had to confess that it was a humiliating circumstance that it should be necessary to establish a branch of the Society in Dublin. It was humiliating to think that the advocates of science should be so hampered in their efforts, and so slandered as to their motives, that a Society of that sort should be needed amongst those who benefited by their labours in the cause of humanity. He regarded the Defence Research Society exactly as he regarded the Society for the Prevention of Cruelty to Children. It was established in the name of humanity, for the sake of suffering mankind, and it was as truly humanitarian as the Society for the Prevention of Cruelty to Children.

Count Plunkett, in seconding the motion, said that it was not proposed to ask for liberty to inflict purposeless pain, nor did they want to defend any wanton action.

The motion, on being put to the meeting, was carried, with two dissentient votes, on a show of

Mr. Stephen Paget, F.R.C.S., Hon. Secretary of the Society, read a letter which he had received from its President, the Earl of Cromer, in which he regretted that he was unable to attend, and eulogised the manner in which Sir Henry Swanzy had worked.

Mr. Paget said he had to convey the congratulations and thanks of the London Committee, and, so far as he could, of the members of the Research Defence Society, to those taking part in the inaugural meeting of the Dublin branch. It was just a year ago that day that the Society drew its first breath. There were seven of them, and they sat round a table that had belonged to Sir James Paget. Referring to the work of the Committee in London, Mr. Paget said the Society had sent their literature and speakers to a great number of debates, but they drew the line at accepting direct challenges from anti-vivisection societies, or arranging with them the terms of a debate, preferring to do their work in their own way. The work of publication was a very important one, but more important than any amount of publishing was the creation of branches up and down the country. During the past year branches had been, or were just being, formed in many important centres, including

Cambridge, Chester, Bournemouth, Oxford, Leeds, Liverpool, Manchester, York, Hull, and Dublin.

Dr. Horne, President of the Royal College of Physicians, moved:—"That the sincere thanks of the Dublin Branch of the Research Defence Society are hereby given to the Right Hon. the Earl of Cromer, President of the Society, for his kind message, conveyed to Mr. Stephen Paget." He congratulated the Society upon having such a man as Lord Cromer for

FEB. 3, 1909.

their President. Referring to experiments on arimals in Ireland, Dr. Horne said the total number of people who were permitted by the laws to experiment was 14, and out of that 14 there were four last year who performed no experiments whatsoever. The total number of experiments performed was 158, and the animals that were used were mice, guinea pigs, rabbits, dogs, goats, and a cat. Mice were the chief objects for making these experiments with. Only three dogs and two goats were experimented u; on. As Mr. Paget had explained, a large number of these experiments were simply innoculations, and that was why mice and guinea pigs and rabbits were the chief animals to be experimented upon. The resolution was carried.

On the motion of the Rev. Thomas A. Finlay, S.J., seconded by Mr. Alexander Blood, K.C., a Committee was formed to work the Dublin Branch of the Society for the ensuing year. The following is the list of the Committee:—Dr. Coleman, C.M.G., Mrs. Frances Dixon, Dr. Frank Dunne, Mr. J. Magee Finny, President of the Royal Academy of Medicine, Mr. Joseph Geoghegan, Dr. Andrew Horne, President of the Royal College of Physicians, Mr. John Lentaigne, President of the Royal College of Faysilians, Mr. John Lentaigne, President of the Royal College of Surgeons, Dr. Lumsden, Professor Mettam, Miss Isabella Mulvany, LL.D., Professor Edmond J. McWeeeney, Count Plunkett, Mr. George Prescott, Dr. Scharff, Mr. L. Edward Steele, Sir Henry R. Swanzy, Professor W. H. Thompson.

University College, Cork.

A MEETING of "Old Corkonians" was held at 20 A MEETING of "Old Corkonians" was held at ao Hanover Square last week, under the Presidency of Sir Thomas Gallwey, M.D., K.C.M.G., to protest against the changing of the name of Queen's Collge, Cork, to the University College, Cork, Dr. Macnaughton-Jones proposed the following resolution: "That this meeting of Old Corkonians has heard with regret of the change in the name of their Alma Mater. Alma Mater. They desire to put on record their indignation at an act which was as uncalled for as it was unjustifiable." He pointed out that if they turned to other new Universities they would find that when Owens College, Yorkshire College, and University College, Liverpool, became part of the new Manchester and Liverpool Universities, they re-

new Manchester and Liverpool Universities, they retained their names. The resolution was seconded by Mr. A. Johnston, LL.B., and carried unanimously. Dr. Charles Haines then proposed: "That this resolution be forwarded to the Right Hon. the Prime Minister, his Excellency the Lord Lieutenant, the Chief Secretary to the Lord Lieutenant in Ireland, the Right Hon. Arthur Balfour, M.P., the President of Queen's College, Cork, and the principal organs of the Press in Ireland." This was seconded and carried unanimously. The proceedings then terminated.

### PASS LISTS.

### Royal College of Physicians, London.

AT a meeting of the Comitia of the College on Thursday last, the L.R.C.P.Lond. was conferred upon eighty-one candidates who have completed the final examination in Medicine, Surgery, and Mid-wifery of the Conjoint Board, and have complied with the ecessary by-laws.

The Diploma in Public Health was conferred upon the following candidates conjointly with the Royal

College of Surgeons at the same meeting:

Alfred Ball, M.B., B.S.Lond., L.R.C.P., M.R.C.S., Alfred Ball, M.B., B.S.Lond., L.R.C.P., M.R.C.S., University College Hospital; Robert James Bethune, M.D., B.Ch., R.U.I., Queen's College, Belfast, and University College Hospital; Arthur Burnell Carter, L.R.C.P., M.R.C.S., Cambridge University and Guy's Hospital; Bertram Walter Cherrett, M.B., B.S.Lond., L.R.C.P., M.R.C.S., St. Bartholomew's Hospital; James Clark, M.D., Ch.B. Aberdeen, M.R.C.P.Lond., Aberdeen University and University College Hospital; James Alfred Patrick Cullen, M.B.Lond., L.R.C.P., M.R.C.S., London Hospital; Leonard Fabian Hirst, M.B., B.S.Lond., L.R.C.P., M.R.C.S., University College Hospital; Duncan Matheson Johnston, L.R.C.P., M.R.C.S., Durham University and St. Bartholomew's Hospital; Andrew Alexander McWhan, M.B., Ch.B.Glas., Glasgow I nisity and University College Hospital; Freuerick Septimus Penny, Captain R.A.M.C., M.B.I ond., L.R.C.P., M.R.C.S., King's College and Royal Army Medical College; Norman Hamilton Walker, M.B., B.S.Lond., L.R.C.P., M.R.C.S., St. Bartholomew's Hospital; Arthur Harold Wilson, L.R.C.P. and S.Edin., L.F.P. and S.Glasg., Birmingham University; Subrahmanyam Yenamandram, L.M. and S. Madras, Madras and King's College.

### Royal Colleges of Physicians and Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.

THE quarterly examinations of the above Board, held in Edinburgh, were completed on January 23rd, with the following results:—

Passed the First Examination.—Hargobind Lal Batra, Kul Bhushan, Edwin W. Marsh, Anthony F. Henriques, Padam A Dastoor, Baboorao G. Shiroadkar, Arthur I. Luke, Maganlal M. Daru, Jugal K. Sharma, Dinshaw B. Gazdar, Erach D. Shroff, Nariman Sharma, Dinshaw B. Gazdar, Erach D. Shroff, Nariman B. Mehta, Kedar Nath, Norman S. Williams, Seringapatam N. S. Aiyangar, Thiruchelvam Sabastian, William Elder, John Hegarty, Hubert W. Ward, Victor T. W. Eagles, Fakir Chand, William A. Reardon, William A. Rees, Hugh W. McH. Wallace, Cyril M. Willmott, Emmanuel P. Ghose, John W. Craig, Furdon F. Keravalla, William P. Over, Prabodh C. Banerjee, and Arthur S. Douglas; and 3 passed in Fhysics, 3 in Biology, and 1 in Chemistry.

Passed the Second Examination.—Eustace Thorp, Tom E. Ferguson, John M. Chrystie, John M. Dalzell.

Tom E. Ferguson, John M. Chrystie, John M. Dalzell, Francis W. Grant, William J. H. Davies, Zebina Annette De Cruz, Edward C. Hamilton, David A. Evans, Narmadashanker P. Vaid, and John Adami; and 2 passed in Anatomy and 5 in Physiology.

Passed the Third Examination.—Bickford J. Hattam, Howard V. A. Gatchell, William Whitfield, William T. Henderson, Hargobind L. Batra, Ernest W. Wilbourne, George B. Moon, Emma M. Johnstone, Daniel Hickey, Kul Bhushan, Edwin W. Marsh, Anthony F. Henriques, and Arthur I. Luke; and 2 passed in Pathology

riques, and Arthur I. Luke; and 2 passed in Pathology and 3 in Materia Medica.

The following passed the Final Examination, and were admitted L.R.C.P.E., L.R.C.S.F., and L.F.P. and S.G.:—Hormusji Jehangir Dadyseth, Bombay; Franklin Joseph de Souza, India; William Forest Mitchell, Derbyshire; Thomas Mitchell Jamieson, Co. Tyrone; Aldington George Curphey, Jamaica; James Bolton Kelso, Co. Derry; William Frederick Buist, Argentine; George Noel Braham, Bath; Kathleen Reed, Calcutta; Hilda Lucy Keane, Bombay; Timothy John Vaughan, Co. Cork; George FitzWilliam Forde, Cork; Harold Ainscough Higginson, Bolton; Henry William Turner, Glasgow; Alexander O'Flaherty, William Turner, Glasgow; Alexander O'Flaherty, Galway; Bhaskar Mahadev Tembe, India; Ernest Gibson, Cork; Edward Corry Wilford, Canada; John Elliott Brown, Jamaica; Abdul Majid Shah, India; Ganesh Vishnu Bhatavadekar, Poona; Hari Ram-Ganesh Vishnu Bhatavadekar, Poona; Hari Ramkrishna Gogte, Bombay; Archibald Davidson, Melbourne; Kaikhusru Sorabshah Commissariatwalla, Bombay; Thomas Brownlie McKendrick, Wishaw; Frank Humphrey Kiddle, India; Dinkar Sakharam Sardesai, Bombay; Peter Stewart, Upnall; Harry Simpson Harling, Castleford; James Aiken, Edinburgh, and Edward John Lumsden, Ireland; and 15 passed in Medicine and Therapeutics, 15 in Surgery and Surgical Anatomy, 30 in Midwifery, and 24 in Medical Jurisprudence.

### Centeint Examinations in Ireland.

THE following candidates have passed the Second Professional Examination of the Royal College of Physicians and the Royal College of Surgeons, Jan., 1900;—T. F. O'Donnell (with honours); J. H. Barry, P. W. Black, P. Daly, J. M. Gilmor, C. J. Halpin, A. Hamilton, C. W. Joynt, C. J. Lanahan, A. G. MacIlwaine, D. McDevett, A. J. Neilan, P. J. O'Connell, D. P. H. Pearson, F. Phelan, C. Roche, P. R. Todd, A. Wiley, F. Webster.

### NOTICES TO CORRESPONDENTS. &c.

Correspondence requiring a reply in this column are particularly requested to make use of a Distinctive Signature or Institut, and to avoid the practice of signing themselves "Reader," "Subsoriber," "Old Subsoriber," etc. Much confusion will be spared by attention to this rule. SUBSCRIPTIONS.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTICEMENTS.

FOR ORE INSERTION:—Whole Page, 25; Half Page, 23 12a,;
Quarter Page, 21 5s.; One-eighth, 13s. 6d.
The following reductions are made for a series:—Whole Page, 13
Insertions, at 23 10a.; 26 at 23 3s.; 52 insertions at 23, and
pro rate for smaller spaces.
Small announcements of Practices, Assistancies, Vacancies,
Books, &c.:—Seven lines or under (70 words), &s. 6d. per
insertion; 6d. per line beyond.
Suppage.—The first woman medical practitioner was Mrs.
Elisabeth Blackwell, who was registered in 1859. Dr. Klisabeth
Blackwell has retired from practice many years. She lives at
Hastings, and is 87 years old. She was born near Bristol, but her
father emigrated to the United States when she was 11 years old.
She decided to become a doctor, and, after a struggle, was accepted
as a student at Geneva College, New York. In 1849 she received
the degree of M.D. from that university, and then studied in
Europe. She practised in America, and there established the
New York Infirmary for Women and Children. In 1858 she
returned to England, wrote "The Laws of Life in Reference to
the Education of Girls," and commenced her friendship with
Mrs. Garrett Anderson.

J. P. Sandlands.—With regard to your further letter, we can
only state that there are limits to our space and to the degree.

J. P. Sandlands.—With regard to your further letter, we can only state that there are limits to our space and to the degree of buffoonery we can permit in our columns.

EXPERIMENTS ON PATIENTS.

### To the Editor of THE MEDICAL PRESS AND CHROULAR.

To the Editor of THE MEDICAL PRESS AND CHROCLAR.

SIR,—Mr. Robbins has altogether run away from the point of argument, and initiated a discussion on his own account, involving issues which concern lawyers more than doctors.

He will observe that I was not discussing the advisability from a legal point of view of a boarding-house proprietor advertising "No thieves here," but started with the comparison between that announcement and the "No experiments on patients." I held, and still hold, that in both cases the public would infer some special immunity from theft and experiments not guaranteed by hospitals and boarding-houses in general, and hence "analogous" cases.

I am, Sir, yours truly,

I am, Sir, yours truly, CLEMENT H. SERS.

Brighton, January 29th, 1909. This letter must close the correspondence.-ED.

• This letter must close the correspondence.—ED.

N. K. (Marble Arch).—The address of the National Truss Society
is 2 Arthur Street West, London, S.E. The Society was founded
in 1786 originally for the relief of the ruptured poor, but its
field of usefulness has been extended to the provision of a large
variety of surgical appliances, such as elastic stockings, kneecaps, catheters, and so on. A subscriber's letter, we regret to
note, has to be obtained by the applicant, who, on presenting
the same, is entitled to skilled advice and the git of an
instrument. There is also the City of London Truss Society,
under the patronage of the King, for the supply of trusses only.
The address is 35 Finsbury Square, London, E.C.
F.R.C.S. (South Molton).—It is an interesting fact that septic
misohief often follows the accidental prick of a thorn, although
it is not easy to see how specific pathogenic microbes should
find a foothold on a thorn outdoors in the country. In some
cases, of course, the infection is secondary. We know of one
case in which a gardener died of acute septio infection two
days after pricking his finger with a rose thorn.

### Meetings of the Socielies, Tectures, &c.

WEDNESDAY, 3RD FEBRUARY.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Clinics: 2.30 p.m: Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks).

THURSDAY, 4TH FEBRUARY.

THURSDAY, 4TH FEBRUARY.

NORTH-EAST LONDON CLINICAL SOCIETY (Prince of Wales's Hospital, Tottenham, N.).—4.15 p.m.: Clinical Cases.

RONTGEN SOCIETY (20. Hanover Square, W.).—8.15 p.m.:
Discussion on the Transport of Ions (opened by Dr. H. Pirie).
NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's teneral Hospital, Tottenham, N.).—2.30 p.m.: Gynscological Operations (Dr. A. E. Glies). Clinics: Medical Out-patient (Dr. A. J. Whiting); urgical (Mr. H. W. Carson); X-Rays.
3 p.m.: Medical In-patient (Dr. G. P. Chappel).
St. John's Hospital. For Diseases of the Skin (Leicester Square, W.C.).—6 p.m.: Chesterfield Lecture: Syphilis: Papular (I.). Miliary; II., Lenticular; III., Squamous; IV., Moist); Pustular, and Tuberculous.

FRIDAY, 5TH FEBRUARY.

FRIDAT, 5TH FERBUARY.

ROTAL SOCIETY OF MEDICINE (LARINGOLOGICAL SECTION) (20, Hanover Square, W.).—5 p.m.: Cases, Specimens, etc.: Will be shown by Dr. Dundas Grant, Sir Felix Semon (with demonstration on epidiascope), Dr. Milligan, Dr. Knowles Renshaw, Dr. Watson Williams, Mr. Clayton Fox, Mr. Chichele Nourse, Dr. Jobson Horne, Mr. Harold Barwell, and others.

ROTAL SOCIETY OF MEDICINE (SECTION OF ANXESTRETICS) (20, Hanover Square, W.).—8.30 p.m.: Meeting: To Consider the Advisability of Legislation to Control the Administration of Anxesthetics.

Advisability Anæsthetics.

Anæsthetics.
West London Medico-Chirurgical Society (West London Hospital, Hammersmith Road, W.).—8 p.m.: Pathological Evening. Specimens shown at 8 p.m.
NORTH-EAST LONDON POST GRADUATE COLLEGE (Prince of Weles's General Hospital, Tottenham, N.).—10 s.m.: Clinic: Surgical Out-patient (Mr. H. Evans). 2.50 p.m.: Operations: (Mr. W. Edmunds). Clinics: Medical Out-patient (Dr. A. G. Auld); Eye (Mr. R. P. Brooks). 3 p.m.: Medical In-patient (Dr. R. M. Leslie).

Saturdat. 6th February.

R. M. Leslie).

SATUBDAY, OTH FEBRUARY.

ROYAL SOCIETY OF MEDICINE (OTOLOGICAL SECTION) (20. Hanover Square, W.).—10 a.m.: Dr. McBride: Dermoid of Mastoid Region. Dr. Dan McKenzie: Notes on the Position of the Patient after Operations on the Mastoid Dr. Kelson: Notes on a Case of White Membranous Deposit in the Auditory Meatus of a Girl. Mr. Hunter Tod and others will show Cases.

### Appointments.

CHEESMAN, EDWARD ROBERT RAMSAY, L.S.A.Lond., Public Vaccinator by the Shafteelury (Dorset) Board of Guardians. COWELL, E. M., M.B., B.S., House Surgeon to University College Hospital.

DANKLS, D. W., M.B., B.S. Long., M.R.C.S. Eng., Casualty House Surgeon at St. Mary's Hospital, Paddington, W.

ELHOTT, T. R., M.D.Cantab., House Physician to University College Hospital.

HERD, HERRY, M.B., Ch.B.Edin., Assistant School Medical Officer to the Manchester Education Committee.

LONGTON, GEORGE HAROLD, M.R.C.S., L.R.C.P.Lond., Honorary Ansesthetist to the Royal Hospital for Diseases of the Chest. MCNAUGHTON, J. G., M.D.Edin., M.R.C.P.Edin., Honorary Assistant Physician to the Manchester Hospital for Consumption and Diseases of the Throat.

RYOATE, DAVID JOHN, L.R.C.P.Lond., M.R.C.S., L.S.A., District Medical Officer by the Williton (Somerset) Board of Guardians. Scott, S. Gilbert, M.R.C.S., L.R.C.P.Lond., Radiographer to the Hospital for Accidents, E., and Honorary Radiographer to the Hospital for Diseases of the Heat, Soho Square.

YONGE, EUGENE S., M.D.Edin., Honorary Physician to the Manchester Hospital for Consumption and Diseases of the Throat.

### Bacancies.

Durham County Asylum.—Junior Assistant Medical Officer. Salary, £150 per annum, with board, laundry, and sttendance. Applications to the Medical Superintendent, Durham County Asylum, Winterton, Ferryhill.

Northampton General Hospital.—Senior Resident Medical Officer. Salary, £120 a year, with apartments, board, washing, and attendance. Applications to C. 8 Risbee, Secretary, Superintendent.

Roxburgh District Asylum, Melrose.—Assistant Medical Officer. Salary, £150 per annum, with board, rooms, and washing. Applications to the Medical Superintendent.

County Asylum, Mickleover, Derby.—Junior Assistant Medical Officer. Salary, £120 per annum, with furnished apartments, board, washing, and attendance. Applications to the Medical Superintendent.

board, washing, and attendance. Applications to the Medical Superintendent.

Cambridgeshire, etc., Asylum.—Senior Assistant Medical Officer. Salary, £150 per annum, with board, lodging, and washing in the Asylum Applicatous to T. Musgrave Francis, Clerk to the Visitors, 18, Emmanuel Street, Cambridge.

West Riding Asylum, Wakefield.—Pathologist and Assistant Medical Officer. Salary, £250 per annum, with board, furnished apartments, and attendance. Applications to the Medical Director at the Asylum.

Northumberland County Asylum, Morpeth.—Junior Assistant Medical Officer. Salary, £120 per annum, with board, apartments, laundry, and attendance. Applications to the Medical Superintendent.

### Marriages.

MORGAN—COWTAN.—On Jan. 28th, at St. George's, Campden Hill,
Conwy Ll. Morgan, M.D.Lond., of The Firs, Droitwich,
younger son of Conwy Lloyd Morgan, F.R.S., LL.D., Principal
of Bristol University College, to Mary, younger daughter of
Frank Cowtan, of 4, Aubrey Road, Kensington.

### Beaths.

MACKAY.—On Jan. 29th. at Lansdowne House. Devizes, the residence of H. J. Mackay, M.D., her step-son, Alice Louisa Mackay, aged 81
READ.—On Jan. 28th. at 11, Petersham Terrace, London. Thomas Lawrence Read, M.R.C.S., aged 76
RUGO.—On Jan. 30th, at Westgate, Ohiohester, Mary Frances Hopestill Rugg, widow of Richard Rugg, Esq., late of Brighton, F.R.C.S.Eng., aged 91.

# Peptogenic Milk Powder

Cows' milk prepared with PEPTOGENIC MILK POWDER becomes remarkably like mothers' milk in all particulars: in physical properties, in colour and taste, and in the percentage of nutritive constituents: in its digestibility, its behaviour with acid, with rennet, and in the infant's stomach.

Milk prepared with the PEPTOGENIC POWDER has simply the normal digestibility of mothers' milk: is not too easily or unnaturally digestible, and contains no aid to digestion. It affords a complete substitute for mothers' milk during the entire nursing period.

Supplied to the Medical Profession in two sizes, at 1/10 and 3/8 each.

# 'Pepsencia'

PEPSENCIA is an ever-ready digestive fluid possessing remarkable peptic and rennet activity. It contains pure pepsin, the vitality of which is unimpaired by chemical action or manipulation, and it is obtained by direct solution from the secreting glands of the gastric mucous membrane, every care being exercised to preserve its full physiological activity.

The usual dose is a teaspoonful before or after meals in all cases where pepsin is indicated. Supplied to the Medical Profession in 4 oz. and 8 oz. bottles, at 1/10 and 3/3 each.

# 'Panopepton'

PANOPEPTON presents the entire substance of prime lean beef and best wheat flour in a perfectly soluble, diffusible, and absorbable form. It is at once a grateful stimulant and food.

For an adult, the usual portion should be a dessertspoonful to a tablespoonful several times a day and at bedtime.

Supplied to the Medical Profession in 6 oz. and 12 oz. bottles, at 2/2 and 3/8 each.

Specimens and literature will be forwarded on request.

Have you noticed that an injection or instillation of

# ARGYROL

(SILVER VITELLIN)

relieves the pain of local inflammation, while all other silver salts increase the pain? Moreover, scientific studies prove that Argyrol quickly destroys gonococci.

These facts explain why Argyrol is considered, the world over, a superior remedy in the treatment of gonorrhoea (injection of 10 per cent. solution every three hours) and other inflammations of the eye, throat, nose and ear (25 per cent. solution instillation or local application).

Produced by

## A. C. BARNES COMPANY

32 SNOW HILL, LONDON, E.C.

The following statement concerning

# OVOFERRIN

(IRON VITELLIN)

is a copy from the official records of the largest clinic in Germany where the remedy has been in continuous use for more than four years:

"Ovoferrin is an easily assimilable, well tolerated remedy which does not disturb digestion or cause constipation, but improves the appetite, digestion and general nutrition, and produces steady and progressive increase in the percentage of hæmoglobin and red corpuscles."

Ovoferrin is furnished by chemists, on prescription, in twelve ounce bottles. The dosage is one tablespoonful in a wine-glass of water or milk three times daily.

Produced by

## A. C. BARNES COMPANY

# Lemco

is offering to its customers (by arrangement with Thermos, Limited) in exchange for Lemco Weight Coupons, a unique and useful article, viz., the

### Lemco Thermos Flask—FREE.

Full Pint size, the same as sold for 1 Guinea.

Free for Weight Coupons representing 7lbs. Lemco. Customers wishing to obtain a flask sooner may send 5lbs. Weight Coupons and deposit of 7/6 or 3lbs. " 10/The Deposit will be returned on receipt of balance of Coupons. Weight Coupons are under capsule on each jar.

The Lemco Thermos Flask is splendid for keeping Lemco hot through the night, for keeping hot liquid food in the night nursery, and for carrying hot bouillon on the motor. Invaluable for invalid and general use. It will keep its contents steaming hot for 24 hours, or icy cold for many days.

LEMCO is pure, fresh beef, in the most perfectly concentrated form known. No preservatives in Lemco, yet it keeps for any length of time. No added flavouring, yet its pure beef flavour makes it appetising beyond compare. Its high concentration makes Lemco the most economical form of beef sold. Owing to its purity and freedom from fat, invalids can retain it when home-made beef-tea nauseates.

This offer is in force till December 31st, 1909.

Doctors should be careful to prescribe "Lemco"—the distinctive Trade Mark by which the original Liebig Company's Extract of Beef is now sold.

Lemco Bonus Office, 4, Lloyd's Avenue, London, E.C.

# Xeroform

**Powder for wounds**; absolutely non-poisonous, non-irritant sterilisable. Applied to aseptic wounds in a thick layer, Xeroform prevents the dressing adhering to the wound, the

aretention of discharge and suppuration along the path of the stitches. In burns, intolerable pain is at once relieved, healing is rapid with very little discharge, and the scar is smooth nd delicate. A specific in moist eczema and in chronic ulcers of the leg.

A rapidly curative remedy, relieving pain, in **rheumatic** troubles; to be rubbed into the skin in muscular rheumatism, acute neuralgia, teno-synovitis, rheumatic pleurisy.

Salit is tolerated by the skin undiluted. No secondary actions.

Novargan

Renders possible a powerfully bactericidal treatment of gonorrhea, for, being non-irritant, it may be used in comparatively high concentration.

disinfects the urinary passages by the liberation of Formal-

Hetralin

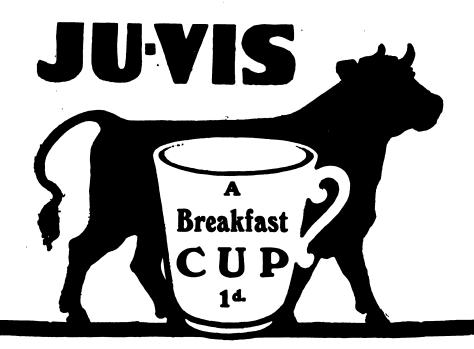

dehyde in acid or alkaline urine; it rapidly imparts an acid reaction to the urine, and it has no irritant action on the

digestive canal or the kidneys.

# FRODUTIN' BRAND Products

'ERNUTIN' is Ergot minus its uncertainties

'Ernutin' presents the active therapeutic principle of Ergot viz. the alkaloid ergotoxine. 'Ernutin' is certain, constant, and reliable. Its action is not restrained, hindered or complicated by the useless constituents of Ergot. The constancy of 'Ernutin' in strength and activity is secured by physiological standardisation.

Clinical reports demonstrate its superiority over ordinary preparations of Ergot

'ERNUTIN' (ORAL)

1 oz. bottle.

Greatly reduced

### After Normal Confinement

'Ernutin' prevents or arrests hæmorrhage, promptly produces a firm contraction of the uterus, improves the tone of the uterine muscle and assists involution. 'Ernutin' does not produce nausea.

### In Post-partum Hæmorrhage

the superiority of 'Ernutin' over Ergot is specially marked. Its rapid, certain and powerful action has saved life when all other means have failed.

### In every Condition

in which Ergot is useful, 'Ernutin' is preferable. For full details, see booklet, "From Ergot to Ernutin," sent post free, on request.

\*ERNUTIN ' (HYPODERMIC)

Box of six hermetically-sealed phials.

Measurements: 2\frac{1}{2} \times 1\frac{3}{4} \times 1\frac{1}{2} \times 1.

'ERNUTIN' Products are supplied to the Medical Profession as follows:

- 'Ernutin' (Oral), in bottles of 1 oz. and 30 c.c., of 2/- ber bottle
- 'Ernutin' (Hypodermic, Berile), in hermetically-sealed phials, min.

10 and 0.6 c.c., in boxes of 6 phials, at 3/- per box

"A distinct advance on Easton's Syrup."

BYNIN' AMARA is an analogue of Easton's Syrup, in which the sugar is replaced by an active Malt Extract. This affords a far better vehicle than syrup, as it is actively digestive and nutritious, and there is not the likelihood of the sugar crystallizing out, and carrying down in the crystal the alkaloid principle.

As a digestive tonic, the efore, 'BYNIN' AMARA is not only safer to take than Easton's Syrup, but is of greater value both in aiding and strengthening the powers of assimilation.

It has been found very effective in neuralgia and similar nerve troubles.

### Notes and Comments.

SOME of the South Shields councillors The South resent the action of the British Shields School Medical Association for suggesting Medical Officer. certain conditions of appointment of

the new school medical officer. One particular point raised a heated discussion the other day, namely, the clause forbidding that official from beginning practice in South Shields within three years of the termination of his appointment. In proposing the rejection of this proposal, a member remarked it had been inserted in the interest neither of the committee nor of the children, and it was no duty of the committee to protect the medical profession. "It was suggested," he continued, "that the medical officer might attempt to insinuate himself into the favour of the parents whose children had been under his attention in school, but he thought he was more likely to increase the practice of other local medical men by discovering physical defects in the children and recommending the parents to obtain medical advice." The seconder of the amendment thought "doctors ought to be allowed to fight their own battles," while one of his supporters described the action of the British Medical Association as trades unionism of a very low level. The amendment was lost by the narrow margin of seven votes to six. So in future the South Shields medical officer may dismiss any idea of settling in that district upon giving up his school appointment.

The Value of School Straws show which way the tide is flowing, and the South Shields councillors reflect with tolerable Appointments. accuracy the attitude of the average

man when the medical profession makes any stand for the protection of its "right to What would these scarcastic councillors say if a sub-committee recommended that engineers, schoolmasters, lawyers, surveyors, and so on, should be brought into their town to hold official posts, with full liberty to compete at any time with citizens already established in the same pursuits? We can imagine the sort of outcry the lawyers would make if a solicitor were thus imported. As to the taunt of trades unionism, we fail to see its relevance. The justice of the principle of collective defence was long ago conceded by the public and endorsed by the legislature. Why, then, should it be derogatory for the profession to follow, albeit longo intervallo, in the footsteps of the lawyers, and attempt to protect its members against certain obviously unfair forms of competition? Another aspect of the matter suggested by the South Shields discussion is the value, or otherwise, of these school posts to medical men. The salary, although enough for a young man, is rarely or never on a scale sufficient for the increasing wants of mature

age, when most men have a wife and family to support. There is small chance of saving money out of the income. The officer is apt to find himself unfit, more or less, for general practice, and has to live for an inadequate present. From many points of view, we should recommend any medical man to weigh the pros and cons of the situation carefully before applying for any post which excludes him from other work.

THE Court of Appeal last Friday The Court of confirmed the decision of Mr. Justice Appeal Channell with regard to the case in on Accidents. which a gentleman who died of pneumonia was held to have died of an accident, within the terms of a policy issued by the Lancashire and Yorkshire Accident Insurance Company. The facts may be briefly recalled. Mr. Etherington, whose executors were plaintiffs in the original case, went hunting after having just recovered from an attack of influenza, and, sustaining a fall on wet ground, but no trauma, promptly became ill. Next day, against medical advice and though he was feeling great pain, Mr. Etherington travelled to London and worked till 6 p.m., when the physical signs of pneumonia developed. Of this disease he died six days later. Now, the policy laid it down that the accident must be the direct or proximate cause of death, and not "when the direct or proximate cause was disease or other intervening cause," although such other cause may have been aggravated by such accident. Lord Justice Farwell, among his remarks, said that it was plain to his mind, on the construction of the primary liability, that the deceased gentleman died from the direct effect of the fall.

Also on Disease.

It is a curious state of affairs which endows His Majesty's judges with a knowledge of pathology in advance of that possessed by physicians. In this case, for instance, we think

that had the policy been one covering influenza and its consequences, but no accident, it might properly have been claimed that the pneumonia was one of those consequences. So that we would have the curious result that the death was due to the accident or the disease, according to how it suited the policy-holder to claim. No event in life is due to one single cause, but to a combination of many causes, and in regarding a death as due to accident, the usual interpretation is that the accident is the effective cause, to the reasonable exclusion of others. It is hardly using words in their proper way to say, for example, that a man in the last stages of cancer died of an "accident" because his nurse dropped a bed-pan on him and he fell dead of syncope. In Mr. Etherington's case it is quite

likely he would have died of post-influenzal pneumonia if he had never left his bedroom, and even more so if he had an ordinary day's hunting without any accident. Moreover, if he had not travelled the next day he might not have died. We confess we have not much sympathy with accident policies which exclude disease, but if people desire and companies issue them, we fancy they ought to be interpreted on some recognised principle, and if the old distinctions between disease and accident are to go by the board, some other rule other than "heads I win, tails you lose" ought to be invented.

At a recent meeting of the Central Departmental Midwives Board a resolution was Committee on passed urging the Lord President of Midwives. the Council to add to the Depart-

mental Committee considering the Midwives Act representatives of general medical practitioners and midwives, as the Board considered that such additions would greatly enhance the value of the report eventually to be made by the Committee. It is not a little paradoxical that a committee should be appointed without such interests being represented, considering that it is they which are almost entirely affected, but when we consider that the State studiously ignores the medical interest in all things pertaining to State medicine, it is not, perhaps, so surprising as first appears. It is troublesome, no doubt, to obtain representatives of a comparatively unorganised body like the midwives, especially considering the com-paratively humble level of education that exists among them, but the difficulty is not insuperable, whereas, in the case of medical men, a good representative general practitioner could be chosen at once from amongst the three gentlemen who are delegated by their brethren to look after their interests on the General Medical Council. The new Lord President might do something to show that he is not a figure-head by promptly remedying this anomalous position.

Dark or Fair?

"BLUE-BLOOD" has long passed into ordinary parlance as a synonym for aristocracy. The expression, of course, is derived from the Spanish,

whose Northern conquerors, and, consequently, whose ruling caste, were fair. The fair, whose blue veins showed through the skin, were the descendants of Visigoths, and therefore masters of the dark aborigines. To this day the flaxen-haired, fresh-complexioned English girl remains the highest type of beauty to Spanish eyes. But the tawny-haired, tawny-bearded giants who came out of the North and conquered Britain, France, Spain, Germany, and even, in the Homeric age, the Greeks, are, the anthropologists would have us believe, a dying race. They are dying out in the towns, and the fresh country blood which is ever setting townwards cannot supply the loss. In a century or two the Angli will no longer be "angeli," but—shall we say—"diaboli"? The smoke, confinement, and irksomeness of town life kills the progeny of the Vikings. If this is indeed so, and there is much to be said in favour of the observation, the outlook for the English is bad. For the change in complexion connotes a change in disposition. The fresh-blooded, eager, restless Northerner will give place to the quiet, inoffensive, humble, short, black-haired Southerner, who can live better under urban conditions. It will be a pitiable thing if the children of the sea-kings cease to be the rulers of their own country and their own empire.

### LEADING ARTICLES.

TUBERCULOSIS AND BRITISH FARMING INTERESTS.

THE issue of the third interim report of the Royal Commission appointed to inquire into the relationsof human and animal tuberculosis marks a further advance in our knowledge of an important subject. Readers may be reminded that the train of eventswhich issued in the Royal Commission originated in the statement of Koch, at the International Medical Congress held in London in 1900, that bovine and human tuberculosis were essentially distinct. Coming from so great an authority, a deliberate utterance of that kind naturally gave riseto world-wide discussion. In England the proposition was at once challenged, and a Royal Commission appointed in August, 1901, with the following terms of reference:—To inquire and report with respect to tuberculosis-

- 1. Whether the disease in animals and man is oneand the same.
- 2. Whether animals and man can be reciprocally infected with it.
- 3. Under what conditions, if at all, the transmission of the disease from animals to man takes place, and what are the circumstances favourable or unfavourable to such transmission.

As regards the first and second terms of the reference, the Commissioners have in their previous reports proved that tuberculosis in the lower animals and in man is essentially one and the same disease, and that the lower animals and man can be reciprocally infected with it. It is hardly possible to overestimate the importance to the community of a conclusive solution of these questions. The Commissioners themselves emphasised various conclusions that must at once follow: - "A very considerable amount of disease and loss of life," they say, "must, especially among the young, be attributed to the consumption of cow's milk containing The milk coming from such a tubercle bacilli. cow ought not to form part of human food, and, indeed, ought not to be used for food at all. Our results point to the necessity of measures morestringent than those at present enforced being taken to prevent the sale or the consumption of such milk." In spite of the publication of that weighty and authoritative warning some time ago, it cannot be said that the State has so far addressed itself seriously to the stamping-out of tuberculous cattle.. The nation goes on subscribing to hospitals and. sanatoria, while the farmers go on distributing tubercle in wholesale fashion throughout the kingdom. The third report is concerned with the third reference. The investigations upon which it is based were carried out by Dr. F. Griffith, upon tuberculous animals purchased by the Commissioners. Tuberculosis of the udder is common, and the milk of cows thus affected always contains: tubercle bacilli. It is now shown that the milk of cows suffering from general tuberculosis, but without local affection of the udder, is at times capable of setting up tuberculosis in guinea pigs. fæces of five out of six tuberculous cows were foundto contain living and virulent tubercle bacilli. Thebearing of this fact upon cow-keeping, both in town and in country, is obviously a fact of first importance. In many ways this little Blue-Book of

thirty-eight pages, constituting the third interim report, is the one that should lead to the practical reform which is the great essential characteristic of British hygiene. One immediate demand will be instruction for our farmers in the whole theory of infection and its prevention, for without the intelligent co-operation of the farmers it will be hopeless to expect any really comprehensive solution of the tuberculosis problem. Anyone who is acquainted with the farming methods of our countrymen will recall a thousand ways in which the infection from tuberculous cows may be communicated to other cows, not to mention pigs, which are often fed with milk from sick cows, and the hundred and one ways in which the milk, even from healthy cows, may become contaminated with tubercle bacilli before it leaves the farm or the town byre. It is to be hoped that the legislature will lose no time in acting upon the information presented by the Royal Commission. It is useless to bewail the scourge of tuberculosis, that forms so serious a drain upon the resources of the nation, unless we take steps at the same time to rid the kingdom of every tuberculous cow within its four corners. Nothing short of rigorous and absolute extermination will meet the necessities of the case. The cost, it is true, will be great, for nothing of the kind could be attempted without compensation to owners. At the same time, the loss to the country would be comparatively small to the destruction of life and health that is going on to a relatively enormous extent year after year owing to the increasing infection of human beings with animal tuberculosis.

### STATE INSURANCE.

Considerable pressure has lately been exercised by the Labour party to induce the Government to start a system of State insurance, and even to make it compulsory on employers to insure their workmen under it. The Home Secretary and the Chancellor of the Exchequer are understood to view the proposal favourably, so much so, indeed, that the great friendly societies are somewhat alarmed lest their domain should be trespassed upon. Last week a declaration by Mr. Lloyd George was read at an Oddfellows' dinner at Warwick, in which occurred the words: - "The Chancellor of the Exchequer asks me to say that in any action which the Government may adopt in regard to insurance against sickness, invalidity, &c., the greatest care will be taken to safeguard the interests of the great friendly societies. Mr. Lloyd George fully appreciates the excellent work which is being done by these societies, and in any scheme which may be devised for supplementing it, has always recognised the importance not only of interfering as little as possible with their present activities, but also of strengthening and encouraging them by every possible means. He is of opinion that these societies form such an invaluable agency of national thrift that it would be a misfortune indeed if anything were done to impair their utility." Now, although with the business of insurance as such medical men are not concerned, yet in the details of any scheme dealing with life, sickness, or accident insurance they will necessarily be intimately associated. We need hardly discuss the question whether such insurance is likely to be done better by the State than by commercial companies. It is, however, pertinent to point out that the present Government plans of life assurance and annuity business are not nearly so attractive as those offered by sound companies which trade for profit. The reason is not difficult to find, for the fact remains that red-tape and absence of stimulus are bound to have a retarding effect in all State concerns. The stability of an insurance office, when well established, is as sure as that of the Exchequer, and enterprising managers make it their business to suit their policies to all the exigencies of national and domestic life. But if the State takes on the work of insurance as proposed, especially if compulsory insurance is insisted on, the interests of medical men must be properly safeguarded. It is held by the Labour party-and in that particular we are in thorough agreement with them-that the State should be a model employer, and that the hours worked, the rate of wages, and the conditions of employment should be those determined by consent with the trades unions, that is, with the representatives of the employées. When the insurance scheme is being prepared, especially in a lean financial year like the present, there will be a determined attempt to cut down the cost of administration, and very properly so. At the same time, the just demands of the medical profession in the way of conditions of employment and of fees must be regarded. The experience of the past has taught us that such interests are grossly neglected in all relations of the State and the profession, whether it be in regard to death certificates, notification of births, or what not. We feel justified in thus early calling the attention of the Chancellor of the Exchequer to this aspect of the matter. It is one which probably has not yet come under his notice, and will, as likely as not, be regarded as a minor point of detail which can be scrambled over without exciting general hostility. We have no doubt, however, that Mr. Lloyd George, who showed himself so wise and fair an administrator at the Board of Trade, is not the man wilfully or lightly to disregard any just claim or fair interest, and he will be well advised to place himself in free communication with representatives of the profession, not necessarily those of the consultant type, and to obtain their views as to conditions acceptable to the medical practitioners. The difficulties of grafting such a scheme on to the present ramification of the insurance business will not be few nor light, especially if the Workmen's Compensation Act, with its many administrative defects, be left unamended; and those difficulties will be enormously multiplied unless the willing co-operation of medical men is obtained. In such work as insurance there does not even exist the question of humanity or good feeling which is always urged as the excuse for imposing burdens on medical practitioners. It is a matter of pure business, and must be dealt with on pure business lines.

### CURRENT TOPICS.

### Report of the Registrar-General for England and Wales, 1907.

THE Seventeenth Annual Report of the Registrar-General, covering the year 1907, contains some noteworthy facts in vital statistics. The feature

likely to attract most attention is the progressive fall in the birth-rate. Since registration became effective the highest point was attained in 1876, when the rate was 36.3 per 1,000 living of the population. Since that year a steady decrease has been registered, and now has fallen to the lowest point on record, namely, 26.27 in 1907. While it would be idle to deny that this state of affairs demands serious consideration, there are, nevertheless, other elements in the situation which suggest that the outlook may be less gloomy than present appearances suggest. Both marriages and births are influenced by the state of the national prosperity, which for some years past has been in a depressed condition. More important, however, are the steady declines in the general and the infantile mortality rates, both of which have in 1907 touched the lowest point hitherto recorded. total result, measured positively, is a lessened rate of mean annual increase in the population of England and Wales to the extent of .42. In the quinquennial period 1876-1880, the average increase was 14.56, which fell to 11.77 in the period 1891-1895, and has thence fallen with slight decimal fluctuations to 11.27 in 1907. At the same time, the mean annual death-rate has fallen from 20.79 in 1876-1880 to 15.00 in 1907. But, as the Registrar-General remarks, while the decrease in births may reach vanishing point, there must be a finality in the decrease of deaths. The decline in infantile mortality is a striking and gratifying feature of the Report. The rate for 1907 is no less than 30 per cent. below the average of the period 1861-1865, the reduction being equal to 28 per cent. amongst males and 32 per cent. amongst females. According to the Registrar-General, this decline has resulted from the passing of the Public Health Act in 1875, by advances in medical science, and by the increased attention paid to hygienic matters by the individual, by local authorities, and by the State. The deaths of infants under one year of age registered in 1907 numbered 109,978, a proportion of 118 per 1,000 births, as against 132 in the preceding year, and an average of 145 in the ten years 1897-1906. As in the general mortality returns the average is seriously diminished by the operation of unfavourable local returns. This point is referred to by the Registrar-General as follows: - "There are several areas in this country, both urban and rural, where the rates are low, and compare favourably with the lowest recorded in the several foreign and Colonial States. On the other hand, there are many industrial centres where the excessive rates indicate that the conservation of infant life is much neglected. It may confidently be affirmed that in future any permanent reduction in the mortality of young children in England and Wales as a whole will largely depend upon a due recognition of parental responsibility on the one hand, and on the other an improved health administration in these industrial areas, particularly in that of numerous small towns." Finally, it may be said generally that, in spite of the falling birth-rate, it is satisfactory to find that the annual mean increase has not materially altered during the past eighteen years. Another noteworthy point in the report is the fact that for the first time for many years there has been a break in the increase of cancer mortality. Amongst children measles has caused more deaths than usual, and scarlet fever, diphtheria and diarrhoeal diseases have been less fatal. The marriage-rate has shown a considerable fall. On the whole, the latest figures of the Registrar-General are distinctly encouraging, although, as we have already pointed out, their full significance cannot be revealed without skilful and painstaking analysis.

### A Notification of Births Prosecution.

An interesting case came before the Belfast Summonses Court last week, in which a midwife and the father of a child were summoned by the Corporation for having failed to notify a birth within twenty-six hours. The midwife testified that the birth took place on October 30th, 1908. The Notification of Births Act was adopted by the Corporation in December, 1907, and came into force in February 1908. Due notice was given to medical men, but the authorities were unable to give notice in writing to the midwives, because they are not registered in Ireland. Special advice, however, had been given to the midwife concerned, and a public warning was published in the newspaper on lune 18th, 1908. It was officially stated in evidence that there was a failure of 30 per cent. in the notification of births, and the authorities were determined to prosecute. In the case under consideration the knowledge of the child's existence was brought to the knowledge of the authorities only when the child was attacked with cerebro-spinal meningitis, and a notification was sent in by the medical attendant. The father pleaded ignorance of the Act, and this being the first prosecution of the kind, no penalty was inflicted, but a fine of five shillings and costs was inflicted upon the midwife. As it was shown clearly in evidence that the midwife had been personally warned as to her responsibility in the matter, she may congratulate herself on having got off so lightly. It seems evident that something more should be done to educate the public as to the meaning of the Act, which in many cases is hopelessly muddled up with that for the registration of births.

Property in Patients.

THERE is a lot of nonsense talked by medical men as regards imagined property in patients, when they come to discuss points of professional ethics. As Mr. Justice Lawrance put it the other day, in summing up the evidence in an action for libel between medical men: - "There was one thing they had learnt from the case, and he thought it would be very useful to all of them: they must remember that when they went to a doctor he thereby acquired some interest in them until the day of their death. It might be desirable, when one went to a doctor, to begin with the remark, 'I am a patient without prejudice.' If they did not say that the doctor might pursue them to the end of their lives." This is very cutting, but we fear we have brought it on ourselves. Many medical men seem to think that once a patient has sought advice from a medical man, he has no right toseek advice elsewhere without express permission. It seems hardly likely that the choice of the public can be thus limited. Let it be said at once that a medical man has no more property in his patient than a lawyer in his client, or a grocerin his customer, and a member of the public is just

as free to choose or change his medical adviser as his man of business, or his grocer. There is, it is true, this difference, that whereas a man may have two grocers at any time, he cannot, from the nature of the case, have two doctors attending him independently for the same ailment, any more than he can commit the charge of a piece of legal business to two solicitors at the same time. We are saying nothing in the slightest degree to excuse the interference of one medical man with the relations between another and those who are, or have been, in his medical care. Such interference is, like other forms of touting for practice, unprofessional in the highest degree.

### The Care of Sane Epileptics.

THE Philanthropic Reform Association had under consideration at its annual meeting the question of the care of destitute and sane epileptics who at present are to be found in workhouses. There are in Irish workhouses between 400 and 500 sane epileptics who are segregated with lunatics and idiots, and whose mental condition has been in many instances seriously affected by their surroundings. In 1901 the Countess of Meath offered a sum of £5,000 towards the initial expenses of building a central home in Ireland for sane epileptics. The offer, however, depended on the amount of support forthcoming from the boards of guardians, which would be expected to contribute to the support of any patients sent by them to the home. The guardians, however, did not give the necessary undertakings, and the offer, though not withdrawn, has not led to any practical results. The Philanthropic Reform Association has decided to ask the Government to make a grant of four shillings per head per week towards the maintenance of every destitute sane epileptic maintained in any home certified by the Local Government Board for Ireland. A very small support from the rates would then enable such homes to be worked satisfactorily, and thus provide reasonable comfort for these unfortunate people. It would also, as Lord Mayo pointed out in proposing the resolution at the meeting, tend to prevent them from becoming inmates of asylums by helping to preserve their mental faculties.

### PERSONAL.

THE PRINCESS OF WALES, on behalf of the National Hospital for the Paralysed and Epileptic, Bloomsbury, has consented to receive purses in aid of the Jubilee Fund some time during the autumn. The amount aimed at by the Jubilee Fund is £50,000, of which £10,000 is to be devoted to the extension of the premises, a commencement of the building having just been made.

Dr. J. E. Gordon has been appointed to the post of Medical Superintendent of the Devon and Cornwall Sanatorium.

Mr. A. G. R. FOULERTON, F.R.C.S., has been appointed Milroy Lecturer at the Royal College of Physicians of London for 1910.

AT a meeting of the Rhondda Education Committee, Dr. J. W. Glenton Myler, of Cardiff, was appointed Medical Examiner of School Children at a yearly salary of £250, rising by annual increments of £25 to £350.

At the annual meeting of the governors of the West Wales Sanatorium, which was held at Carmarthen, under the presidency of Sir James Williams-Drummond, Bart., Lord-Lieutenant of Carmarthenshire, Dr. Bowen Jones received a handsome presentation in recognition of his work for the institution.

AT a meeting of the Senate of the University of London, held on January 27th, the Vice-Chancellor, Sir William Collins, M.D., M.P., in the chair, Mr. G. H. Cowen, M.B., M.S., was appointed member of the Council of Hartley University College, Southampton, and Mrs. Scharlieb, M.D., M.S., Governor of St. Mary's College, Paddington.

Miss Muriel Robertson was appointed at the same meeting to be one of the assistants to the Professor of Protozoology in place of Dr. J. D. Thomson, resigned; and a letter was received from Dr. P. H. Pye-Smith, M.D., F.R.C.P., F.R.S., intimating his resignation of his membership of the Senate as one of the representatives of the Royal College of Physicians of London.

On February 2nd, the Director-General of the Royal Army Medical Corps and the members of the Royal Army Medical College entertained at dinner Viscount Midleton, who, as Secretary of State for War, founded the college. Amongst other guests present were Sir William Nicholson. Chief of the General Staff; Sir Herbert Miles, 'Sir A. Wynne, General Browne, Sir James Crichton-Browne, and Lord Edmund Talbot.

THE Presidential Address at the next annual meeting of the British Medical Association will be delivered by Sir William Whitla, M.D., LL.D., Professor of Materia Medica and Therapeutics, Queen's College, Belfast; the Address in Medicine by Frederick Taylor, M.D., F.R.C.P., Consulting Physician, Guy's Hospital; the Address in Obstetrics by Sir John Byers, M.D., Professor of Midwifery and Diseases of Women, Queen's College, Belfast; and the Popular Lecture by J. A. Macdonald, M.D., M.Ch., Physician to the Taunton and Somerset Hospital, Chairman of the representative meeting.

The following Fellows of the College of Physicians have been elected Councillors: Sir William Allchin, in the place of the late Dr. C. E. Beevor; Dr. Sidney Phillips, Dr. W. Pasteur, Dr. S. Martin, and Dr. A. E. Garrod, in the place of Dr. W. Osler, Dr. Crocker, Dr. Tooth, and Dr. Acland, who retire by rotation.

At the same time Dr. F. H. Champneys was reelected to represent the College on the Central Midwives Board; and Dr. C. Theodore Williams was elected a representative on the Court of Governors of the University of Birmingham.

AT a large gathering of those interested in ambulance work at Oxford, Dr. J. C. R. Freeborn, the chief Honorary Surgeon of the corps, was made the recipient of a presentation which had been subscribed for by friends and pupils.

MAJOR RONALD Ross, Professor of Tropical Medicine in the University of Liverpool, has been invited by the Governor of Bombay to proceed to that city to take part in the deliberations of the Indian Medical Congress. The committee of the school have arranged for Major Ross to accept the invitation, and he left for Bombay on February 3rd.

### A CLINICAL LECTURE

ON

### INTUSSUSCEPTION. (a)

By DENIS KENNEDY, F.R.C.S.L.,

### Surgeon to Jervis Street Hospital and to the Children's Hospital, Dublin.

Intussusception is a form of intestinal obstruction that has a very high mortality. This high mortality can be accounted for :-

(1) The disease usually occurs in infants or young

children.

(2) The diagnosis is not made sufficiently early for treatment to be effective.

(3) Purgatives are frequently administered be-

cause of faulty diagnosis. (4) Valuable time is sometimes lost in treating the disease by measures that will almost certainly

be ineffective. Varieties of Intussusception .- There are four

varieties of intussusception:

(a) Enteric—when the trouble is confined to the small bowel.

(b) Colic—when the trouble is altogether in the large bowel.

(c) Ileo-colic-when the ileum slips into the colon through the ileo-cæcal valve, and the intussusception is increased at the expense of the small bowel.

(d) Ileo-cæcal—when the ileum and cæcum, preceded by the ileo-cæcal valve, with, of course, the vermiform appendix, slips into the large bowel, and the invagination is continued entirely at the expense of the colon. This is the most common variety, and constitutes close on 40 per cent, of the cases.

Ætiology.—Sometimes intussusception is started by a polypus in the lumen of the bowel; sometimes it may be caused by intestinal worms; sometimes by the increased peristalsis associated with acute enteritis; but in a large number of cases one cannot say what really is the exciting factor in the disease. In all cases it is impossible to recognise the presence of the cause until the intussusception has occurred. Hence, as clinicians, we are principally concerned with the pathological changes that take place, with the symptoms that are produced, and with the best

means of saving our patient's life.

Pathological Changes.-The first essential pathological change that occurs is the invagination of the bowel above into the lumen of the bowel below. This can be easily illustrated with the finger of a kid glove. In the process of invagination serous surface is opposed to serous surface, and mucous surface to mucous surface. On a transverse section there will be three concentric rings of bowel, and, of course, there will be three layers of intestine on either side of the central canal. The outer layer of bowel is called the intussuscepiens, or sheath, and the middle or returning layer, with the inner layer, constitute the intussusceptum. In all varieties, with the exception of the ileo-colic, the invagination progresses at the expense of the "sheath." Thus, in the ileo-cæcal variety the ileocæcal valve may protrude through the anus, the Intussusception having progressed at the expense of the colon. Other important pathological factors must also be considered. The invaginated bowel is practically in a condition of strangulation. The mesentery being drawn with the bowel, its blood-

A point not to be forgotten is, that the longer an intussusception is left unreduced, the more difficult reduction becomes, and ultimately reduction will become utterly impossible. This is brought about at first by the swelling of the invaginated bowel on account of its strangulation, and later by adhesions that form between the opposing surfaces of in-

testine.

The intussuscepiens, or sheath, does not undergo gross pathological changes. It becomes congested, more friable, and is very easily torn in attempts to

reduce the intussusception.

Symptoms.—The gravity of the initial symptoms depends, as in all sudden abdominal lesions, on the amount of injury done to the viscera involved; in other words, on the amount of bowel invaginated. Consequently, in some cases the early symptoms may not be severe, and the diagnosis symptoms may not be severe, and the diagnosis may be missed. Sudden pain in the abdomen, associated with more or less collapse, occurring in a child that has been previously healthy, should always make us suspect the trouble. In an infant, unaccountable fits of crying with great restlessness are the early symptoms. When the disease is developed we get the typical symptoms of intestinal obstruction, as far as regards the collapsed condition of the patient, the facial aspect, and the continuous vomiting. But there are a few well-marked symptoms that will differentiate intussusception from any other abdominal lesion :-

(1) There is the frequent passage per anum of blood and mucus, and, consequently, instead of getting a history of constipation, we get the opposite, of diarrhœa.

(2) There is always present an abdominal tumour.

There is tenesmus.

(4) Vomiting in the beginning, at all events, is not persistent and does not become fæcal for a considerable time. (5) The intussusception may be felt on making a

digital examination of the rectum.

vessels become subject to pressure at the neck of the intussusception. At first this pressure is only sufficient to interfere with the return of venous blood. In consequence, the invaginated bowel becomes engorged with blood and greatly swollen; hæmorrhage occurs from the engorged blood-vessels into the lumen of the bowel, and this hæmorrhage, which becomes mixed with the increased mucus that is poured out from the congested mucous membrane of the intestine, is passed per anum, and forms the discharge, "bloody mucus," which is so characteristic of the disease. As the swelling of the intussuscepien increases, the pressure on the mesenteric vessels will become greater, and after some time the arterial supply will be completely cut off. The intussuscepted gut becomes strangulated, gangrenous patches will then appear on the invaginated bowel, and finally sloughing of the whole mass may ensue if the patient lives for a sufficient time. In this way Nature can possibly effect a cure; but so rarely does this event occur that we must not allow it to enter into our minds in the treatment of the disease.

<sup>(</sup>a) Delivered at the Jervis Street Hospital, November 3rd, 1908.

(5) The abdomen does not become distended, as a rule.

The key to making an early diagnosis is the palpation of the abdominal tumour. As I have said, it is always present, but usually can be felt in the early stage of the disease, only on the administration of an anæsthetic-chloroform for choice. By giving the suspected child chloroform, and by making a careful abdominal and rectal examination, we can be as certain of the presence or absence of intussusception as if we made an exploratory laparotomy, by the presence or absence of this abdominal tumour. It is the absence of this examination with the patient anæsthetised that accounts for the large number of cases of intussusception that are not diagnosed until it is too late for treatment to be effective. I well remember the case of a little boy, three years old, who was brought to three general hospitals in the city, and two practitioners, during three days. In each place either a purgative or astringent was ordered. The little patient, not improving, was brought to a maternity hospital, where the condition was accurately diagnosed, and the patient was sent at once to the Children's Hospital for operation. I operated the same night, but, needless to add, I was unable to save the patient's life.

Prognosis.—The prognosis depends on the disease being diagnosed early, and on the patient being promptly and efficiently operated on. In the absence of early operation, the disease is nearly invariably fatal in a few days. The age of the patient must be taken into consideration, as young infants under six months old stand abdominal operations badly.

TREATMENT.

In treating intussusception, the practitioner must remember that there are things he must not do, as well as things he must do. He must not give purgatives. Castor oil or calomel is frequently ordered, because the condition is mistaken for acute enteritis. Secondly, the less nourishment that is given by the mouth the better. Unless a sip of water, nothing else is admissible.

With regard to what ought to be done, I am firmly convinced that the only satisfactory or effectual treatment is operative. The abdomen should be opened and the invagination reduced manually. In reducing the intussusception, care must be taken to be as gentle as possible; it is easy to tear the intussuscepien. The best way to effect reduction is by pressing back the invaginated bowel, beginning at the apex. Previous to operation, but when the case has been diagnosed, a hypodermic of morphia may be given with advantage. It relieves pain and checks peristalsis, which will prevent the intussusception being increased. It must, however, be borne in mind, that children bear morphia or opium badly.

bear morphia or opium badly.

I do not think it possible for an intussusception to be reduced by the injection of air or gas or water through the rectum. When anyone who has frequently operated on these cases sees the difficulty of reducing the invagination, even when the abdomen is opened, he must come to the conclusion that reduction by means of anything injected through the rectum is utterly impossible. There are two dangers in connection with these attempts at reduction by injections through the rectum: One: valuable time is lost and false hopes are held out to the patient's parents; the other: it is not unknown for the bowel to have been ruptured by the pressure of the injection being too great.

With regard to what ought to be done if the reduction of the intussusception is impossible, I think no hard and fast rule can be laid down.

Every case will have to be treated on its own merits. The age of the patient, the amount of collapse, the length of time elapsed since the beginning of the illness, the condition of the bowel involved, will all have to be considered in coming to a decision.

One of three or four procedures may be carried

(1) Resection of the irreducible mass and making an artificial anus.

(2) Resection of the mass and performing an anastomosis, either end-to-end, or lateral.

(3) Where the invaginated bowel is not gangrenous, nor liable to become so, as sometimes occurs in chronic intussusception, a short-circuiting of the bowel can be done by an anastomosis between the bowel above and the bowel below, leaving the irreducible intussusception alone.

leaving the irreducible intussusception alone.

(4) Probably the operation that will be applicable to the greatest number of irreducible cases is that known as Jessett's or Barker's. The principle of this operation consists in splitting the intussuscepiens on the anti-mesenteric border of the bowel, cutting away the intussusception right to the neck; then the edges of what remains of the middle and internal layers are sutured together. This checks any bleeding that may occur. The operation is completed by suturing the opening that was made in the intussusceptiens. It is the most rapid method of dealing with an irreducible intussusception, and at the same time having an efficient restoration of the continuity of the bowel.

In any operation for intussuception we must deal with any abnormal condition that may have been the cause of the trouble. If a polypus is felt in the lumen of the bowel, it must be removed; or if a Meckel's diverticulum is present it should be resected.

Special precautions should also be taken to prevent shock. The limbs and chest of the patient should be swathed in absorbent wool; the operation should be carried out rapidly, as a child bears a prolonged operation very badly; no unnecessary handling of the small intestine should occur, and on no account should evisceration be allowed to take place. Sometimes in a young child it is difficult to prevent some of the distended coils of intestine becoming protruded when the abdomen is opened; this is especially the case if the child is not completely anæsthetised. If escape of some intestine should occur, it should be wrapped round with gauze wrung out of hot saline solution, until its return can be completely effected.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Prof. H. Chauffard, M.D., Physician to the Paris Hospitals. Subject: "Moningeal Hamorrhage."

International Congress of Ophthalmology.

WE are asked to intimate that an effort is being made to arrange special terms for travelling expenses and hotel accommodation for the benefit of those who may wish to attend the above Congress, which will be in session at Naples from March and to April 7th. We would also remind our readers that it is proposed to issue for perusal before the meeting the communications which are offered for discussion at Naples. These will only be sent to those who have signified their intention to be present and have paid the Congress subscription in advance (25 francs for members and 10 francs for each accompanying member of a family). To facilitate these arrangements it is most desirable that those who wish to attend should make the earliest possible intimation to one of the corresponding members for Great Britain and Ireland: Walter H. Jessop, 73 Harley Street, London, W.; Dr. George Mackey, 20 Drumsheugh Gardens, Edinburgh; or Sir Henry Swanzy, 23 Merrion Square, Dublin.

### ORIGINAL PAPERS.

A CONSIDERATION OF SOME OF THE MORE RECENT WORK ON

### IMMUNITY, ESPECIALLY IN RELATION TO DIAGNOSIS AND TREATMENT. (a)

By Prof. ROBT. MUIR, M.D. Ed., F.R.C.P.E.,

Professor of Pathology in the University of Glasgow.

PROFESSOR MUIR commenced his paper by stating that immunity to ordinary infections is due to two things, namely: (1) reactions on the part of the cells of the body, and (2) resulting changes in the serum of the blood. Regarding the nature of the first of these we know practically nothing, in fact, nearly all the recently-acquired knowledge on this subject is with regard to the changes that take

place in the blood serum.

After pointing out that not only bacteria themselves, but the toxins they gave rise to, were very complex bodies, and that no anti-substances could be formed in the blood to any substance of known chemical constitution, the lecturer described the condition of immunity, and contrasted it with the condition we are familiar with as tolerance. Tolerance was a kind of acclimatisation either to surroundings or to conditions that were normally injurious; or to taking substances into the body that acted in an injurious manner upon the tissues. In tolerance there are no anti-substances formed in the blood. In immunity, on the other hand, anti-substances which neutralise the effects of bacteria or of their toxins are formed in the blood, and the condition of immunity to infection depends upon their action. The molecules which give rise to anti-substances are generally known as antigens. Not all toxins have anti-substances formed when they get into the blood, so that, as far as is known, there is nothing that can neutralise the harmful effects of some bacteria. Toxins which act as antigens soon disappear from the blood after being injected; this is largely due to their combining with or fixed to the cells of the body. The anti-substances then begin to develop in the blood serum. These neutralise the effects of the toxins and bring about a state of immunity, which may last for a very long time after the anti-substances have all disappeared from the blood. This state of immunity consists of several well-defined periods. There is first a latent period during which the toxin is be-coming fixed. This is followed by a period of rapid formation of anti-substances. Then there is a period during which this condition is maintained, which is followed by a period during which antisubstances are formed more and more slowly, and gradually disappear from the blood entirely. again is followed by a period of immunity during which no anti-substances are found in the blood. The crisis in infectious diseases probably corresponds to the second period of immunity, when the anti-substances are rapidly formed.

When anti-substances are being developed, say, in response to the injection of toxin, the state of immunity can be greatly increased by the injection of moderate doses of the toxin at intervals. In this increase or intensification of immunity there are two phases, a positive and a negative. The injection of a moderate dose of toxin is followed by the negative phase of immunity. This is a diminution in the amount of anti-substances in the blood, caused by the direct neutralisation of a portion of the anti-substances by the new antigens injected. It

(a)"Abstract of, paper read before the Glasgow Medico-Chirurgical Society, January 22nd, 1909.

does not go the length of making the state of immunity disappear, but simply causes a depression which is soon followed by the positive phase of immunity. During this phase anti-substances are formed in greater quantity than before, so that the condition of immunity is exalted to a higher level than it reached before the injection of the toxin. This can be repeated at intervals till the state of immunity is very high, as long as only moderate doses of the toxin are used. When a large dose of toxin is injected the effect is different, for the result may be a negative phase only, which may be so great that it may cause complete failure in the formation of anti-substances.

The changes that take place in the cells of the body, which keep up the condition of immunity after the disappearance of anti-substances from the blood, are comparatively unknown; the discussion of the possible explanations must be left over. The anti-substances are, therefore, substances which are formed in the serum of the blood as a reaction to toxins, &c., and they are only formed when the toxin has certain molecules in its composition, which act as antigens. It is therefore the antigens that give rise to the anti-substances. This relation of antigen to anti-substance is one of specific combining affinity. Only one particular anti-substance can be produced as the result of the presence of any particular antigen in the blood. This specificity particular antigen in the blood. is remarkable, and is the outstanding feature of the phenomena observed in the production of immunity, though the nature of the combination is still the subject of controversy. While the nature of the anti-substance never varies when any particular form of bacterium or toxin is injected into the blood, the quantity of the anti-substance varies greatly in different individuals and in different The amount of anti-substance developed may be in great excess of the amount of toxin or antigen introduced into the body—a fact of which no satisfactory explanation can be given.

In contra-distinction to the condition of immunity, there is a condition called anaphylaxis. This is a state in which the cells of the body are hypersensitive to infections, that is, there is a diminution of the normal resistance to the action of bacteria or other toxins. It is different from what we understand by idiosyncrasy, and different also from what we regard as the cumulative effect of injurious substances introduced into the body. exact nature is still unknown, but in this condition there is in the tissues of the body a want of resistance to the action of bacteria or their toxins. This condition can be brought about by the injection of small quantities of toxin at intervals; thus, very small doses of the diphtheria toxin injected at intervals may cause a marked hypersensitiveness to the diphtheria toxin. A condition allied to anaphylaxis is well marked in patients who are suffering from any form of tubercular disease, as both the tuberculin reaction of Koch and the ophthalmic reaction of Calmette depend on it for their diagnostic value. The reactions in these tests are due to the excessive sensitiveness of the tissues to the action of the tubercle toxin, when there has been small quantities of this present in the tissues for some time. All the tissues of the body are rendered hypersensitive by the action of the toxin in tubercular patients. The "Theobald Smith phenomenon," which consists in the extraordinary sensitiveness produced in the guinea-pig to horse serum by the previous injection of a minute quantity of the serum, was also referred to as the most remarkable example of anaphylaxis.

There are two different kinds of immunity, or two different ways in which immunity may be brought about, depending on the source of the anti-

substances. When the anti-substances are developed in the immune animal itself the resulting condition is called active immunity. When the anti-sub-stances are not developed in the immune animal, but are transferred from another animal to the immune animal, the resulting condition is called passive immunity. Active immunity is produced by vaccines, which are a modification of the virus that causes the disease; and this immunity by vaccines is used as a prophylactic measure in such diseases as plague, typhoid and cholera. In this method of producing active immunity, cultures of the bacteria that cause the disease are used in small quantity, and these may be dead, as in plague or typhoid, or they may be living, as in cholera. The small quantity of virus introduced into the body is capable of giving rise to a large amount of anti-substance in the blood, and these anti-substances which accompany the condition of immunity can be observed, differentiated, and measured.

There are found to be five different varieties of

anti-substances, and these differences depend on the nature of the action of the anti-substances. varieties are, namely: (1) Anti-toxins; (2) precipitins; (3) agglutinins; (4) opsonins; (5) immune bodies. The agglutinins, opsonins, and immune bodies are all produced by the presence of bacteria in the blood. Their presence and amount can be readily ascertained, and they are of considerable value in diagnosing and prognosing several im-

portant diseases.

(1) Anti-toxins are anti-substances which unite with the corresponding toxins and render them inert; the most important example is the anti-toxin

example of diphtheria.

(2) Precipitins are formed in the blood of one animal by injecting the serum of another animal of a different species. For every species of animal the reaction is comparatively specific. This specificity is very remarkable, and advantage of it is taken to determine the source of blood in blood-stains for forensic purposes. The reaction is obtained by using the very minutest quantities of the animal's blood.

(3) Agglutinins are formed in the blood by the presence of bacteria in the body. The reaction is very marked, and may be present as early as the fifth day in typhoid fever. It is very delicate, and an important diagnostic test; but while the agglu-tinins indicate the presence of the virus, they pro-bably do not destroy the substance causing the disease.

- (4) Opsoning are anti-substances developed in the blood which enable the phagocytes to devour the bacteria when present. They are of two chief types, namely: (a) The opsonins of normal sera; and (b) the opsonins of immune sera, which differ from those of normal sera in withstanding heat, and in being specific. The presence of opsonins in the blood is necessary for the occurrence of the phenomenon of phagocytosis. Under the stimulus of the opsonins of normal serum the phagocytes can attack and destroy many foreign substances that may be introduced into the body; but the specific phagocytic activity towards a particular organism is stimulated only by its own specific opsonin formed in an immune serum.
- (5) Immune bodies. These are anti-substances concerned in bactericidal action and hæmolysis, along with the complement of normal serum. This complement of normal serum is essential for the destruction of red blood corpuscles and bacteria, and is easily destroyed by heat. It is brought into union with the bacterium by means of the immunebody, which acts as a link (amboceptor) or as a sensitiser. The presence of the complement is de-tected by hæmolysis; thus, if the red blood corpuscles of one species of animal be injected into

the blood of an animal of another species, the immune-body formed in the serum of the host's blood, along with complement normally present, causes solution of the foreign red blood corpuscles. If, however, the serum of the host's blood be first heated the complement is destroyed, and its power of dissolving the foreign red blood corpuscles is lost by the serum; this power is, however, restored by the addition of fresh normal serum. complement is taken up or fixed when an antigen and its anti-substance neutralise each other; and haemolysis is stopped by the complement being deviated from the red blood corpuscles. Thus a very minute amount of human serum, along with its anti-serum (precipitin), will fix complement, and thus interfere with hæmolysis. The differentiation of the blood of different species of animals for forensic purposes depends on these phenomena, and they are also made use of in the diagnosis of some diseases. In order that an anti-bacterial serum be bactericidal it is essential both that it contains an immune-body which will bring the complement of the person treated into union with the bacterium, and also that this complement should have a destructive action on the bacterium; these conditions are rarely satisfied. (The original complement of the anti-bacterial serum soon becomes destroyed when the serum is kept, and its place has to be supplied by the complement of the person injected.) He then referred to the method introduced by Mackenzie and Martin of treating epidemic meningitis by injecting into the spinal canal some of the fresh serum of the patient. The method is sound in principle, inasmuch as the serum contains immune-body and also complement, and has a direct bactericidal action on the meningococcus; the actual results are also encouraging. The serum diagnosis of syphilis by means of the deviation of complement was then described and explained.

Treatment by Anti-toxic and Anti-bacterial Sera. -Professor Muir then made some remarks on the treatment of diseases by anti-toxic and anti-bacterial sera. He pointed out that it was not every toxin that had an anti-substance developed by its presence in the blood; and even when a toxin had an antisubstance developed, this, to be effective in producing cure, must be used before the toxin gets fixed in the cells of the body; this is the explanation of the comparative non-success of anti-tetanus In speaking of anti-bacterial sera, he serum. stated that the human complement does not kill the staphylococcus, nor does this organism give rise to any anti-substance that can destroy it. Here the complement is not active, and Professor Muir supposes that any benefit derived from the injection of anti-staphylococcus serum is due to the opsonins present in it allowing of greater phagocytosis, and not to any destruction of the virus by substances in

the serum injected.

The opsonic methods of Wright for the production and estimation of active immunity by vaccines during an infection were then considered; atreptic immunity was thereafter explained. This is an immunity depending on the absence of some substance necessary for the growth of the invading organism. Some the growth of the invading organism. Some organisms require a very specialised medium for their growth, and when this is no longer present their activity ceases and they die out. Thus many organisms that produce diseases in man simply die out when injected into animals of other species. This probably accounts for the inability to develop syphilis, for example, in most of the lower animals. The bacillus of influenza will not grow in an agar medium, but if this be smeared with blood it then grows quite well. So cancer from the mouse can go on growing for a time in the rat till the particular substance it requires for its growth becomes exhausted. It then dies out in that animal. The serum reactions were demonstrated as far as possible in test tubes and under the microscope.

### THE AURAL COMPLICATIONS OF IN-FLUENZA AND THEIR TREATMENT.

By HAROLD F. MOLE, F.R.C.S. Eng.,

Assistant Surgeon to, and Surgeon in charge of the Aural Department, Bristol Royal Infirmary.

Now that the influenza season is again upon us, it seems not unfitting to call attention, in a very brief way, to the various ear troubles it may give rise to, especially as these form a fairly frequent complication of this affection. (a) Amongst adults it is one of the commonest causes of suppurative otitis, and probably accounts for more of this trouble in children than is generally supposed; and particularly is this the case in those suffering from adenoids. Common catarrhs, adenoids, measles and scarlet fever are, however, more frequent causes in children. Although there are some peculiarities in influenzal otitis to which attention must be called, there is, however, no very material difference in treatment between it and that due to other specific affections.

Influenza may set up acute otitis media by way of the Eustachian tube, which may be non-suppurative or suppurative, the latter being the more

With regard to the former, the symptoms are acute pain in the ear, with congestion of the drum, and probably blocked Eustachian tube and deafness. The treatment to be adopted will be that of antiseptic sprays or irrigations to the naso-pharynx, leeches to the front and back of the ear (if the symptoms are severe), instillation of a few drops of warmed carbolised glycerine into the meatus, and hot dry applications over the ear. A brisk aperient should also be administered. As the acute symptoms subside, the ear should be gently inflated by Politzerising or catheter—preferably the latter, as it is more accurate, and the force of the inflation can be better regulated.

The evidence of case-histories shows that this acute non-suppurative otitis caused by influenza is not infrequently the precursor of chronic adhesive middle-ear catarrh. It is, therefore, of the utmost importance to treat it with the greatest care in the early stages, and not to let the patient pass from one's hands until cured.

Suppurative otitis media in influenza is often characterised by the extreme acuteness of the process with ecchymosis, and the formation of hemorrhagic blebs on the drum and on the deeper parts of the meatus, and also by its great tendency to involve the mastoid process. Accompanying these appearances are intense pain of neuralgic character, and, of course, deafness, the latter often coming on more gradually than in other forms of otitis. Another peculiar feature is that this pain is not always immediately relieved when the drum has burst or has been incised, which is the case in other forms of suppurating ears. The early treatment of these cases should be the same as mentioned above in the non-suppurative variety. A careful watch must, however, be kept for signs of suppuration, and persisting intense pain or bulging drum should be treated by free incision of the membrane from top to bottom behind the handle of the malleus. This treatment is far better than allowing the drum to perforate, since it is followed by immediate drainage, and healing occurs more quickly

than in the case of spontaneous perforation. As mentioned above, however, the pain may persist for a few days after the incision. The treatment after incision will depend upon the fancy of the surgeon, and the conditions under which it must be carried out. When the surgeon is able to carry this out himself, thorough cleansing and drying of the ear, and packing down to the perforation with a strip of moist antiseptic gauze as often as is necessary, is perhaps the best. This, however, is seldom possible, and when, as more often happens, the patient's friends have to carry out the treatment, I am in the habit of ordering irrigations (not syringing) of warm boric lotion, carried out frequently, a large quantity of lotion being used each time. The frequency with which this should be carried out will depend upon the amount of disphare. If the inciding is free or the amount of discharge. If the incision is free or the perforation large, it is often unnecessary to order any other treatment than this, as the discharge rapidly diminishes, and the perforation heals in a week or two or less. When, however, all the acute symptoms have passed, and the discharge is much diminished but the perforation is sluggish in healing, a little boric powder may be insufflated, or some glycerine of carbolic acid, I in Io, instilled after the ear has been cleansed and dried. When the perforation is spontaneous and small, and especially if it is at the apex of a nipple-like projection of the drum, it should be enlarged by incision; but if this is not indicated, and the perforation is still small, the best plan is to instill proposition of human and the perforation of human and the perforation of human and the perforation of human and the performance peroxide of hydrogen (hydrozone and perhydrol are strong solutions of the same) for fifteen minutes; mop dry or syringe, and then instil for a similar period a few drops of glycerine of carbolic acid, I in 10, or of glycerine of borax with 2 drachms of absolute alcohol to the ounce. Irrigation and syringing are not of much value when the perforation is small; they only cleanse the meatus. After the perforation has firmly healed it will probably be found necessary to carry out a course of inflations through the Eustachian tube for a time, to completely restore the hearing. If there are not, after three weeks of the above treatment, clear indications that the affection is coming to an end and the perforation closing, it must be assumed either that the antrum is not draining properly through the tympanum, or that the mastoid pro-cess is involved. Under these circumstances the antrum must be opened and drained for a time, and the tympanic cavity washed out by this route.

As before mentioned, one of the peculiarities of influenzal otitis is its tendency to involve the mastoid process. This involvement may take place before there is any perforation of the drum, or, indeed, although rarely, without there being any discharge from the meatus. It may involve the mastoid cells without there being any obvious communication with the tympanum, and it may cause rapid destruction of the bone, early exposing the lateral sinus or dura mater, and giving rise to any of the ordinary intracranial complications. The diagnosis of influenzal mastoiditis is not always easy, and it must be remembered that pain and tenderness over the mastoid at the commencement of the ear trouble will often subside under active antiphlogistic treatment if there is a free opening Temperature is very little guide, as in the drum. it is often subnormal, with the mastoid full of pus and carious bone. A persisting tenderness after the first few days with no abatement in the discharge, with or without swelling, and cedema over the mastoid process, indicates operation without delay. In most cases it will be found necessary to remove the whole of the outer cortex of the mastoid from apex to antrum. Should a specially tender

<sup>(</sup>a) "Bristol Medico-Chirurgical Journal." September, 1908.

spot be noticed, this may be explored first, for the abscess may then be localised. I have seen cases in which the mastoid cells were filled with pus and carious and necrotic bone, and the antrum unaffected, and apparently unconnected with them. After removal of the cortex, all diseased bone should be thoroughly scraped away, and the cavity packed with gauze. It will, of course, be understood that in the acute cases I have been discussing the ossicles are not interfered with nor the drum, unless it is necessary to enlarge an opening in the latter. In this short sketch the intracranial complications cannot be discussed.

Finally, there are those cases of post-influenzal deafness which, on examination, are found to be of nervous origin. They are probably due to a neuritis of the auditory nerve, though some are supposed to be caused by changes in the labyrinth. There is not infrequently severe timitus with them. In this case the treatment consists in the administration of strychnine, either hypodermically or by the mouth. The treatment must be persisted in for some weeks, and the quantity increased gradually until a full dose is reached.

entir a run dose is reached.

# THE PHYSIOLOGICAL IMPORTANCE OF THE PROSTATE.

By Prof. C. POSNER, M.D.,

[SPECIALLY REPORTED FOR THIS JOURNAL.]

The results, very worthy of consideration, that the surgical treatment of so-called hypertrophy of the prostate have achieved during recent years, have again drawn attention to the question: What is the true purpose of the prostate gland in the organism? The experiences of surgeons have repeatedly given a direction to our general physiological views, and we ought to again bring to mind the knowledge, far beyond that of the region affected, that the operative treatment of enlarged thyroids has brought to us. As the symptoms of deprivation were the first to throw a light on the action of the normal thyroid, we might expect here that the extirpation of the prostate and the consequences of it would show us in what the function of this organ properly consists—a question to which physiology has hitherto failed to give a perfectly satisfactory answer.

The matter here is indeed not quite so simple as in extirpation of the thyroid. Men for whom it had been decided to remove the prostate were mostly men of very advanced age, and of them it could be assumed, in advance, that those functions that were connected with sexual life were already in decadence, so that their elimination without something further would

not make itself seen.

Then, in the so-called hypertrophy of the prostate the matter was not one of simple increase in size, but of pathological new growths, of tumours, which had at last changed the proper structure of the gland, so that in effect extirpation did not affect this, but a

tumour that had taken its place.

It is very remarkable how slight the symptoms of deprivation usually are in the individual clinical case. In cases that run a smooth course, there is usually nothing to be noticed as soon as the disturbances caused by the wound have passed away. Not only does the bladder regain its full power, even when the patient has been reduced to the use of the catheter for years, but the general condition improves so much that one is justified in speaking of a "second youth" of these patients. And when the sexual functions suffered, so far as they came into consideration, and when, in particular, impotentia generandi set in, we were more inclined to attribute it to unavoidable injury of the exit passages than to a deeper inward disturbance.

The fact that the bladder does not lose its power of closing after extirpation of the prostate is very remarkable. This observation is in unison with what we see in those castrated early (eunuchs): it shows

most decidedly that the prostate, as such, has nothing to do with closure of the bladder. For long it was believed that such a function must be attributed to it—now it seems no longer doubtful that its muscular parts have another purpose to serve, viz., that of ejaculation. Even if prostatectomy has as yet furnished no materials for determining the other functions of the prostate, it has at least given fresh cause for extensive experiments on animals, from which some clearness in regard to the question pending has already been obtained. Even earlier than this, German inquirers—I mention Disselhorst and Steinach in the first rank—have entered upon this path; more recently, and at the instance of Albarran, a large quantity of material in this direction has been brought forward by two Spanish authors, Serralach and Parès, which may be allowed to be a base for hypotheses, even if the conclusions may be not quite indisputable.

First of all, these investigations, as well as the earlier ones, have again brought proof that things are very different in the different kinds of animals, and that, in particular, a remarkable interchangeable relation exists between the prostate and the seminal vesicles; it appears as if these two organs could to a certain extent replace each other. In animals with large prostates the vesicles are almost, if not altogether absent, whilst in animals with small ones they are very strongly developed. It is possible that much of the prostatic preparations in the market is actually prepared from the seminal vesicles! For the study of the symptoms of deprivation it has, at any rate, been shown to be advantageous to consider the two organs as a whole and to extirpate them together.

In animals sexually mature (rats, dogs, etc.), this operation has made its influence appear in the first instance on the spermatogenesis and the potentia. The elaboration of semen ceases and the sexual impulse is extinguished; the secretion given off in attempts at intercourse contains no spermatozoa. Feeding with prostatic substance, however, revives both these functions; they may even revive spontaneously, but the authors attribute this to retained vestiges of tissue and regeneration of the glands. With these varied experiments agreeing in their ultimate effects, the proof was adduced that in the prostate we have a gland with "internal secretion," the action of which on the genital organs proper appears to have been proved.

Are the observations made on the human subject in accord with these discoveries from experiment?

The existence of a mutual interaction between the testicles and the prostate has long been known. I have already mentioned the fact, known to everybody, that in eunuchs the prostate is scarcely developed at all, as normally, it only reaches maturity at the time of puberty, simultaneously with the development of spermatogenesis. On account of this fact the "sexual operation" has long been carried out, from which the surgeon has promised himself that atrophy of the gland, that late in life becomes swollen and "hypertrophied," will take place—a deceptive expectation that I must emphasise, as the growth is not simply glandular tissue, but tumour mass; retrogression may be expected at most when the tumour mass is mostly of an adenomatous nature.

The question seems to me more important whether inversely an affection of the prostate—atrophy of it or aplasia—might lead to arrest of the sexual function

in the human subject.

I shall here at first attribute no importance to the symptoms resulting from ordinary chronic prostatitis so frequently observed, amongst which impotentia cœundi plays an important rôle. Complicated nervous processes of the most varied kind may here be also in play, and when we see that local treatment directed to this, that massage of the prostate, combined with hydrotherapeutic and general strengthening measures, bring about recovery, we may well doubt whether the loss of power can really be reckoned amongst the symptoms of deprivation. It seems to me more necessary in the study of these things, to limit ourselves to the cases in which spermatogenesis also ceases, where deviations from the normal are distinctly present.

In determining the symptom of azoospermia, until lately, we could only examine the ejaculated semen. We had a compound terminal product before us; and when the spermatozoa were absent, we could not decide whether they had not been developed or whether there was some mechanical hindrance to their outward passage. By far the greatest number of cases were easily explainable in the latter way; it was almost always possible to make out some remains of bilateral epididymitis, that simply prevented the passage of the newly-formed spermatozoa. There were also cases in which there was no history or trace of previous inflammation or trace of cicatrix that could cause any obstacle. We first discovered an exact distinction between these two groups, in diagnostic puncture of the testicle, first introduced by J. Cohn and myself. A good deal of experience has shown that by puncture of the testicle we can almost obtain proof as to whether spermatozoa have been formed or not; I have made repeated reports on this subject, but I would also draw attention to the inaugural dissertation of my son, Dr. H. L. Posner, in which, amongst other things, it is shown that in the healthy individual one never looks in vain for spermatozoa in the puncture fluid.

Those cases that give a negative result after explora-tory puncture are the first to interest us. In the dissertation mentioned there are seven such cases. I have observed several more since they were noted. Hitherto we were in some difficulty as to what to advise in such cases; in general we assumed a primary imperfect development of the testicles, a real absence of sperma-togenesis. For some time I have paid special attention to the prostate in such cases, and have found that this was almost always remarkably small, atrophic or aplastic. This being so, we must either assume a common arrest of development, or that the primary seat of the trouble must be sought in the prostate; the absence of the prostatic substance (its glandular part) would then be the cause of the aspermia. The cause for this absence, again, is difficult to determine. I incline to the assumption that there has been in many cases a previous prostatitis, and here I would emphasise that it need not by any means always be of a gonorrhœal nature, but that it may arise through other infections (B. coli), or it may be "aseptic," for example, from simple retention of the prostatic secretion. Stern has observed, to give a clinical illustra-tion, that prostatitis is a very frequent occurrence in diabetics, as I have also shown as regards the so-called prostatic hypertrophy. Is it not likely that the impotentia generandi of these patients may all be explained in the way pointed out? Supported as we are by animal experiment, we shall be justified in drawing therapeutical conclusions from the foregoing. At least in such cases we should try the internal employment of a useful preparation of the prostate, or Poehl's spermine, a medication that should be as rational in such cases as the giving of thyroid is in diseases set up by deficiency of that organ. Although it was observed at the commencement that the symptoms of deprivation were but slight after prostatectomy, in order to avoid misunderstanding, it may be mentioned here that in such cases we have to do mostly with old men, in whom, even without operation, the sexual functions would be failing or lost altogether. It will now be understood that, in spite of escape from injury on the part of the exit passages, impotence may occur, and, on the other hand, power may be retained when residua of the prostate gland are left. Animal experiment appears to show, further, that a close connection exists between the prostate and the bladder; the removal of the prostate causes paralysis of the bladder as a symptom of deprivation. This point is much in need of further clearing up; as, willingly as one would the so-called faux prostatiques of Guyon of patients who suffer from symptoms of prostatismus, in spite of the prostate being remarkably small, in this way, however much Goldberg's group of prostatistis cystoparetica may invite us, we must look, on the other hand, at our surgical experiences. After prostatectomy we see the bladder that has been paralysed for years and dilated to its maximum regain its full muscular strength. Further investigations are required to explain this contradiction, and especially to determine how far the nerves of the prostate are implicated.

Further knowledge of the functions of the prostate should also be expected from the experiments at implantation recently made by Haberer, after total extirpation of the organ. As the locality for implantation in my opinion—after the procedure of Kocher in Basedow thyreoidea—in the dog, the epimetaphesis of the femur should be considered. Neisser has already shown a mutual action between the prost te and bone marrow. No positive results as to the effects of implantation are before us.

In contrast to these questions that are essentially concerned with the subject of "internal secretion," the interest as regards the proper function of the secretion of the gland has dropped behind. The assumption, based on the observations of Fürbringer, that there is some relationship to the vitality of the spermatozoa, is undoubtedly justified; but it is questionable whether the matter is one of simple dilution of the semen (and thus one of osmosis) or of a specific ferment. The presence of lecithin in the secretion of the prostate may be evidence in favour of this; such an excitation is set up by it, as we have learned to recognise lecithin as an exciter of ferment. But we must not look upon this action as something altogether indispensable. I have repeatedly found living spermatozoa in spermatoceles, as well as recently in puncture fluid from the testicle.

In my address before the Paris Congress of Urologists, I pointed out that possibly another function—one little thought of or but little understood—was to be attributed to the prostate. It perhaps represents an analogue of the rut glands so strongly developed in many mammals. That the secretion of the gland is that which gives the specific odour to the semen has been shown by Fübringer; this odorous material has apparently lost its original significance in the human subject, whilst similar substances play a great rôle as sexual exciters in the animal world. I have already observed that (according to Disselhorst), in the hedgehog, for example, the corresponding aromatic substance is actually produced in the prostate, whilst otherwise it is mostly the cloacal glands that are concerned. From this point of view the prostate would

be looked on as a residual organ, that has, perhaps, at one time had higher functions than it has to-day in the human subject.

### **OPERATING THEATRES.**

KING'S COLLEGE HOSPITAL.

**OPERATION** FOR VISCEROPTOSIS.-MR. ALBERT CARLESS operated on a woman, set. 45, who had been sent into hospital with a story of urinary trouble; occasionally she went for a day or two without passing water, and during these periods her doctor stated he was unable to draw off water by catheter, and at the dropped into the pelvis. This was associated with a certain amount of pain and discomfort. This story on the face of it, Mr. Carless remarked, read like that of displacement downwards of a single kidney, followed by kinking of the ureter and dilatation of the pelvis of the kidney, with retained urine. The patient was a well-nourished woman, and had been kept under observation for a week or more. She was made to get up and move about the ward and do some dusting in the hope of bringing about a repetition of the above-stated phenomena; nothing, however, abnormal had occurred. On palpation neither kidney could be felt, and there was no obvious mobility; the abdominal wall, however, was very loose and relaxed, and hung down in a sort of pouch, into which the intestines dropped. It was possible to grasp a large handful of the abdominal wall, and on releasing one's hold the intestines could be felt to drop downwards, with pain in the back to the patient. The woman had had four children, and this condition of the belly wall was the outcome of the pregnancies. Under these conditions, Mr. Carless thought it advisable to deal first with the abdominal wall and tighten it up effectively, taking the opportunity at the same time of exploring the abdominal

The operation was as follows: -A free incision was made in the middle line from a little above the umbilicus to a point just above the symphysis pubis; this incision was subsequently increased upwards. The linea alba was found to be much stretched, and replaced by a fibrous aponeurosis extending between the margin of the recti muscles, which were separated by an interval of two or three inches. The aponeurosis was split in the middle line, and the peritoneal cavity opened. Examination of the abdominal contents revealed the facts that the left kidney was abnormally mobile, but of normal size and with no evidence of hydronephrosis; that the right kidney was normal in size and shape and not unduly mobile; that the gallbladder contained a good many small calculi; and that there was nothing obviously wrong with the rest of the viscera. It was decided merely to deal with the abdominal wall at this operation, and if subsequently symptoms arose the left kidney and gall-bladder would have to be dealt with separately.

The method of dealing with the abdominal wall was as follows: The skin and subcutaneous tissues were separated on each side from the muscles and aponeuroses as far as the linea semilunaris; a silk mattrass suture was then passed through the margin of the aponeurosis representing the linea alba, and the underlying peritoneum and the loose ends carried by a long, full-curved hernia needle through the abdominal wall on the other side, as near to the linea semi-lunaris as possible. A series of these sutures were passed from below upwards, and tied as they were passed. The result of this was to make the two halves of the abdominal wall to overlap; in this case the patient was sufficiently fat to interfere with this being effected as perfectly as in some other cases that Mr. Carless mentioned. Some trouble arose from some of the stitches being carried through the rectus muscle instead of through the linea semilunaris, thereby wounding some of the veins within the muscle substance, and necessitating a troublesome search for the bleeding point. When the right flap had been effectively secured by sutures under the left, the margin of the latter flap was effectively stitched down to the outer aspect of the right linea semilunaris and sheath of the right rectus. It was then found that the skin and subcutaneous tissues were much too abundant to cover in the abdominal wall, and therefore a large flap of this, about 6 in. broad in the centre, was excised by a curved incision reaching from one end of the wound to the other. The opposite flap of skin and subcutaneous tissue was laid down in this space and secured in place by sutures. A drainage tube was inserted for 24 hours, and the wound dressed in the usual way.

Mr. Carless commented on the extremely satisfactory

results which followed operation of this character. He had performed it now a good many times, and was much pleased with it. Practically it consisted in overlapping the abdominal parietes in a manner similar to that which would transform a single-breasted to a double-breasted coat. The anterior portion of the abdominal wall has its strength thereby doubled, and the extensive removal of skin and subcutaneous tissue will assist in keeping the parts taut. Care has, of course, to be taken in the passage of the deep sutures not to wound viscera nor to allow omentum or intestine to become entangled in the threads.

It is interesting to note that this patient's wound has healed perfectly, and remained firm in spite of an acute attack of bronchitis.

### Legislation Against Street Noises.

WE have received from the Street Noise Abatement Committee a petition to the Prime Minister, urging immediate legislation respecting unnecessary and objectionable street noises, especially including noisy and dangerous motor-omnibus traffic, street shouting, and organ-grinding. It is signed by about 500 representative noblemen, members of Parliament, solicitors, merchants, hotel proprietors, etc., and by about 100 representative members of the medical profession.

### TRANSACTIONS OF SOCIETIES.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD WEDNESDAY, FEBRUARY 3RD, 1909.

The President, Dr. JAMES RITCHIE, in the Chair.

MR. J. M. COTTERILL opened a discussion on THE TREATMENT OF VARICOSE VEINS OF THE LOWER EXTREMITIES.

He referred shortly to the pathology of the condition, and pointed out that we were still to a large extent ignorant of the cause of varix in many cases. Still, we could divide causes into predisposing and exciting, among which he enumerated as the most frequent heart disease, pregnancy, abdominal tumours, and occupations necessitating continuous standing. In connection with treatment, the general health required attention; tonics, bathing, regulated exercise, were all in place. The actual local treatment of varix was either palliative or radical. He pointed out that when palliative treatment was once begun, it was generally necessary to carry it out for the rest of the patient's life. He thought, therefore, that when the varicose veins were small, confined to the lower leg, and giving rise to no discomfort, it was not necessary to treat them locally at all, particularly as there was in many cases a tendency towards natural improvement in later life. Palliative treatment consisted in the application of a support. He preferred a Martin's bandage, though a few patients could not tolerate it. It must be applied carefully, and both it and the leg to which it was applied must be thoroughly cleansed every time it was put on. If perspiration was troublesome he sometimes applied it over a cotton stocking, which was renewed and washed daily. Failing a Martin's bandage, an elastic stocking should be used. It was convenient, but care must be taken that it fitted properly, because, if it did not, the pressure was applied unequally. The radical treatment of varix might be divided into that of simple cases and that of cases complicated by thrombosis or phlebitis. In simple cases the degree of regurgitation of blood could be simply measured by Trendelenburg's test. The limb was held upright for three minutes to empty it of blood, and then a pad was applied to the saphenous vein in the thigh. When the patient stood erect, the pad was removed, and the rate at which the blood filled the vein was noted. The operation he advised was the ligature and removal of an inch of vein in one, two, or three places, as required. It was particularly important to maintain thorough asepsis, and to keep the patient in bed for three weeks to avoid the risk of embolus. The operation should not be undertaken without due consideration in gouty sub-When an ulcer was present, it was advisable to wait until it was healed; another contra-indication was the existence of thrombosis of the deep tibial veins. In cases complicated by thrombosis, rest in bed for a period of about three weeks or more was required. If, in spite of rest, the thrombosis seemed to be spreading up the leg, it was a question whether it was not advisable to try to hinder its spread by removing a piece of the vein above. When, however, thrombosis was due to some blood condition, as in typhoid, he questioned whether operation would be justified, as a fresh thrombosis might develop at the point of ligature. In simple phlebitis rest was all that was needed. In phlebitis leading to local suppuration and abscess formation, operation might be tried. In infective phlebitis it was advisable to try to check the process by ligature and excision of a piece of the vein. In operating high up, however, there was always the danger of dislodging a

piece of thrombus into the femoral vein.

Dr. George Hunter spoke of the importance of attending to anæmia in cases of thrombosis, mentioning as a particular instance the case of a bleeding fibroid causing varicose veins, anæmia, and thrombosis.

Mr. Downen preferred a crape bandage to an elastic one. He had in several instances been compelled to tie the saphenous vein close to the femoral, and had had no trouble with thrombus formation. He thought that thrombosis was often due to infection with

organisms of low vitality.

Mr. Scot Skirving urged the special importance of asepsis in vein operations. He had in several cases employed Mayo's subcutaneous method, but had failed with it when the vessel wall was friable.

Mr. STRUTHERS inquired as to the ultimate results of operation. In out-patient practice a great number of patients had varicose veins which gave no discomfort, and a good many were seen who had been operated on at one time or another and had relapsed. Hospital patients so quickly passed from under observation that it was not easy to say how many were permanently cured. He also asked whether, and in what way, excision of varicose veins healed varicose ulcers.

Dr. NORMAN WALKER also inquired whether radical

treatment of varicose veins really tended to cure vari-cose dermatitis and ulcer. A number of those cases came under him in the skin wards, and if he could be assured that operation would check recurrence he would urge it more strongly than heretofore

MAYO'S OPERATION. Mr. GEO. CHIENE described Mayo's operation, and showed the special instruments devised. He advocated the operation on the ground that it was more radical, and took a shorter time, than excision of parts of a Of 40 cases of varix operated on, 20 by Phelps' operation and 20 by Mayo's operation, he had traced 30, and the results were on the whole better after the former procedure.

Drs. DARLING and ARMOUR preferred crape or web-

bing to Martin's bandage.

Dr. CHALMERS WATSON asked why gout should be looked upon as a contra-indication to radical measures? Gouty persons stood operation perfectly well.

Dr. Jamieson asked in what proportion of patients

embolism actually occurred?

The President thought it was desirable to institute palliative measures, even if there were no symptoms, in order to prevent the patient's condition becoming worse as time went on. He referred to two cases of

worse as time went on. The referred to two cases of serious embolus occurring in his practice

Mr. COTTERILL, in reply, said that the form of bandage used was not of great importance, though, with the qualifications stated, he preferred Martin's bandage. He thought the operation he employed sufficiently radical, and was satisfied with the results it gave. Mayo's operation was unnecessarily severe. The ulcers which resulted from varicose veins might be due to a vicious circle, in which blood returning from the leg flowed back in the saphenous vein without being purified. He had followed up a number of being purified. cases, and in most the results were permanently beneficial. He quite agreed as to the need for treating anæmia in cases of thrombosis. With regard to the danger of embolism, he had not seen this occur from thrombosed varix. He had once seen a fatal embolism occur in an elderly man from thrombosis arising in connection with a fracture. He thought that after three weeks' rest there was little risk of embolus taking He thought that after place.

Drs. G. A. GIBSON and W. T. RITCHIE communicated an account of a

CASE OF STOKES-ADAMS' DISEASE due to partial heart-block. The main features of the case (which was of historic interest as having occurred in the person of a prominent member of the medical profession) were as follows:—The patient had enjoyed good health, and had led an active life until over 70. He was suddenly seized with an epileptiform attack rigidity and unconsciousness lasting for over an hourwith a pulse of only 6 per minute. He gradually re-covered from this, but after an interval of some months the attacks recurred. Ultimately he developed a persistently infrequent pulse (32 per minute), without any further syncopal attacks. From his own record of his case it appeared that the attacks were unaccompanied by any sensation of faintness, of angina sine dolore, or of impending death. He never had Cheyne-Stokes' respiration. His alimentary, respiratory, nervous, and urinary symptoms were normal. The heart was enlarged and the apex beat forcible. There was a shrill systolic bruit in the mitral area, propagated to

the tricuspid region; the aortic second sound was accentuated; during the ventricular pause the auricular contractions could be heard. The pulse varied between 28 and 32 per minute. The systolic blood pressure was high (230 mm. Hg.); the diastolic low (70 mm. Hg.). The jugular pulse was always of the auricular type. A number of tracings illustrating the circulatory phenomena were shown. The radial pulse tracings showed that the beats were not quite rhythmical; on the descending limb of the tracing auricular waves appeared. These, however, were better seen in the tracings from the apex beat. Comparison of the venous and radial trace showed a complete disassociation of the action of the auricles and ventricles, the carotid wave occurring at regular intervals without reference to the auricular pulse. For the sake of comparison, tracings from similar cases were thrown on the screen. One of them illustrated the action of atropine on the auricles but not on the ventricles, in heart-block. The auricles were beating at the rate of 230, the ventricles at 16 per minute. Tracings taken by means of Einthoven's string galvanometer (electrocardiograms) in cases of heart-block, lent by Professor Einthoven were also shown. Dr. Ritchie described the pathological changes which were formed, and demonstrated the lesion of the auriculo-ventricular bundle, etc., by means of lantern slides.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF ANATOMY AND PHYSIOLOGY

MEETING HELD FRIDAY, JANUARY 22ND, 1909.

The President, Dr. T. H. MILROY, in the Chair. THE PRESIDENT, having thanked the Section for the honour conferred upon him in his election to the Presidency, said he wished to put before the members the result of some work which he had done on reaction time, and which he had undertaken in order to study the nature of mental fatigue.

FATIGUE DURING REACTION TIME EXPERIMENTS.

By reaction time is meant the period which elapses between the initiation of a sensory stimulus and a volitional motor response on the part of the stimulated individual. Thus one might estimate this time for hearing, sight, or touch, taking the same type of motor response as indicator in each case. When a series of reaction times are taken for any of the above-mentioned senses, one observes that there are naturally distinct variations in the intervals between the sensory stimuli and the motor responses; but one may also observe that in all cases, after a prolonged series has been taken, fatigue gradually sets in, as shown by a lengthening of the reaction time. This fatigue might affect the sensory paths, the sensory centres, the intermediate central paths between these centres and the voluntary motor centres, or the motor path as far as the muscles themselves. The experiments were carried out in order to arrive at some knowledge as to the most probable seat of the fatigue. In all cases a preliminary series of reaction time experiments was taken in order to obtain an average normal result. Then, following such a series, various devices were employed in order to fatigue, if possible, mainly the sensory, then in another series mainly the intermediate central paths, and, in still another, the motor paths. The following may be taken as an example of the procedure adopted in connection with the analysis of the fatigue produced during reaction time for hearing experiments. At first the average normal reaction time for hearing was obtained. Then the person was asked to follow carefully the ticks of a metronome beating regularly, and to keep count of the beats. This could be done without straining attention beyond a very slight extent. After varying periods of this metronome counting the reaction time for hearing was again taken. It was found that there was practically no lengthening of the reaction time, even after the person had listened to the metronome for one hour. In another series of experiments the person was asked to count the irregular ticks produced by toothed wheels acting on one

another, the speed at which those were driven being varied. After varying periods of this form of sound production, the reaction time for hearing was again taken. It was found that, even after shorter periods than in the case of the metronome, slight fatigue was produced as shown by the lengthening of the reaction time. In still another series the reaction time for hearing experiments itself was used throughout to produce the fatigue, and it was found that the lengthening of the reaction time took place much more rapidly than was the case in the immediately preceding series. principal difference in the nature of the three series was the degree of attention which was required to be directed towards the act. This was least in the first series and greatest in the last. It was then deemed advisable to study the effects of interpolating between two series of reaction times for hearing, a series of similar ones for sight, or between two series of sight reactions, one for hearing. In practically all cases a change of this character did not prevent or even delay the usual onset of fatigue. In fact, if there was more variation than the above-mentioned in the reaction times series—as, for example, hearing, sight hearing, sight—the lengthening in the last series of reaction times for sight was greater than it would probably have been had reaction times for sight been taken throughout the whole experiment. In these experiments the sensory paths were varied, the central in part varied, while the motor path remained the same. Although the central path was varied in so far as a transmission had to take place from a different sensory centre to the same motor one, there was one central system common to all—namely, that concerned in directing attention to the translation from the sense perception to the volitional act. Therefore, as the sensory channels have been changed, and the path from sensory centre to voluntary motor centre also varied, if these changes mean rest to the unemployed paths, then fatigue must have affected either the higher neurone systems concerned in the maintenance of what we term "attention," or the neurones concerned in the transmission of the motor impulses. That it is not the latter is shown by the results of certain experiments which were carried out with the view of fatiguing, if possible, the motor path without affecting to any marked extent the higher centres concerned in the maintenance of attention. This was done by asking the person to carry out similar motor acts to those employed in the ordinary reaction time experiments. No sign of fatigue was to be observed, as judged by the average duration of reaction time, before and after such a period of motor activity. An example of the degrees of fatigue produced by changing from one form of reaction time to another (the motor response in each case being the same) may be given—(1) Normal reaction time for sight, .206 seconds (average over twenty-five minutes; experiment 250 observations). (2) Subsequent reaction time for hearing, .225 seconds taken for ten minutes (the normal for hearing being below .200 seconds). (3) Continuation of (2) for another ten minutes, reaction time (hearing) .267 seconds. (4) Reaction time for sight taken in conclusion for a period of ten minutes, .271 seconds. This degree of fatigue from .206 seconds to .271 seconds is probably not less than would have occurred had reaction times for sight been taken throughout the whole experiment. From a careful study of a large number of experiments on the reaction time, it appears as if in all cases the fatigue has its seat in the higher centres concerned in the direction of the attention towards the sensory motor reaction. These higher centres appear to be required in order to link the These higher various synapses of the higher psychical and volitional motor centres more closely together, and thus facilitate the transmission of the nervous impulses. in their fatigue there is a delay in transmission probably due to the higher resistance at the synapses, which are not so closely linked together as when the attention is freshly directed towards the act at the outset of the

Professor Dixon expressed the thanks of the Section to the President for throwing so clear a light on the action between neurones; his method of tackling the

problem was undoubtedly the right one.

Professor Fraser said there was a great difference between the effect of a bell sounding for dinner and a burglar alarm at night, although the path was the same.

Dr. Dawson said that if the President's theory was correct it would appear that the site of the evil, so far as it had a local habitation, must be somewhat

higher than the faculty of attention.

Dr. WALTER SMITH said that the fundamental value of the communication appeared to be its introduction of quantitative measurements into the estimation of psychological and sensual processes. In judging of reaction time, an important factor was the duration of the stimulus. There was a great difference between the momentary impact of a visual stimulus and the relatively long duration of even the shortest sound. The subject was valuable to physicians and surgeons in estimating the phenomenon of knee-jerk, or the many manifestations of disordered and delayed sensations in hysteria. A most important point was the fatigue in the synapses between neurones. It was possible to draw an analogy between mental and digestive processes: in the nervous system they might recognise the possibility of a stimulus of stimili just as there was in the digestive system a ferment of ferment.

Dr. MOORHEAD said he strongly believed that after a short rest following work one could turn to a new variety of work that required just as much attention, whereas if one turned to the same kind of work the same power of attention would not be appreciated.

The PRESIDENT, in reply, said the nature of impressions varied according to the stimulus. One's idea of certain sounds was based on past sensations and memories which called forth a different mental condi-There were certainly two paths between neural centres, one voluntary, the other formed by habit, but they could not say whether the linkage was always made by the one path, nor could they recognise where volition came in. His tests were for the purpose of finding where fatigue occurred, not to find what alterations in duration of stimuli produced—that had been carefully worked out by others. It was difficult to tell how change gave rest. Sight plus hearing would produce greater fatigue than one form of fatigue carried the whole way down.

### NOTES ON THE STERNO-CLAVICULAR JOINT.

Dr. H. M. Johnston gave a communication on the above joint, and exhibited drawings in illustration of the interesting points brought forward regarding the anatomy of the articulation and the movements of the The security of the joint was shown to depend mainly upon the costo-clavicular ligament, which penu mainty upon the costo-clavicular figament, which is always tense, even when the upper extremity is hanging by the side. Owing to the attachment of this ligament to the clavicle being on the posterior-inferior aspect, elevation of the clavicle is permitted by a movement of rotation taking place, during which the anterior surface of the bone becomes directed somewhat anterior surface of the bone becomes directed somewhat upwards. The interarticular meniscus, intervening between the inner end of the clavicle and the sternum and first costal cartilage, and against which, owing to the laxity of the capsular ligament, the articular surface of the clavicle can move (upwards and downwards, forwards and backwards) serves rather as a "buffer," preventing shocks and jars being transmitted to the sternum, than as a ligament. To the sternum and costal cartilage (this meniscus intervening) the inner end of the clavicle seems to be, as a general rule, firmly applied. During pulling, and when supporting the weight of the body by hanging from the hands, the clavicle is drawn somewhat outwards. occur during reaching movements, as the contraction of the subclavius muscle prevents the clavicle being drawn away from the sternum as the scapula moves This fact can be readily outwards and forwards. demonstrated in the living subject.

Professor Dixon stated that he had seen the dissections of the joint made by Dr. Johnston, and was convinced that the explanations given of the function

of the costo-clavicular ligament and of the subclavius muscle were the correct ones.

Professor FRASER, Dr. MOORHEAD, and the SECRETARY expressed their appreciation of the work done, and of the interesting nature of the conclusions submitted by Dr. Johnston.

In replying, Dr. Johnston called attention to the fact that the nerve-supply of the subclavius muscle was from the same source (5 and 6 C, as the upper part of the serratus magnus, which muscle was so intimately associated with the reaching forward movements.

#### DORSAL SUBCLAVIAN ARTERY.

Professor M'Loughlin exhibited a specimen of the above. There were three branches from the arch of the aorta. The first branch was a stout trunk, 6 mm long and 22 mm. wide, which gave off the two common carotid arteries: the second branch, which lay against the first, was the left subclavian, and the third branch, 12 mm. behind the second, was the irregular right subclavian.

DUODENAL DIVERTICULUM.

Professor M'Loughlin next exhibited a specimen of duodenal diverticulum. The opening was oval (16 mm. by 13 mm.), and was situated between the bile papilla and the caruncula minor, the centre of the opening being 10 mm. above and to the left of the former, and 12.5 mm. below and to the right of the latter. The hood-like valvula connivers above the bile papilla passed down the right wall of the diverticulum. The upper boundary of the opening was sharply defined by a curving valvula connivens, the sac passing up underneath this overhanging edge. The lower and left walls of the sac sloped gradually on to the somewhar smooth mucous membrane of the duodenum below. The depth of the diverticulum was 18 mm. On being dissected from the back, the diverticulum was found to be embedded in the head of the pancreas, and supported behind in its right half by the bile duct. The duct of Wirsung coming down through the head of the pancreas swept to the right round the lower part of the diverticulum, and there joined the bile duct about 12 mm. from the opening on the bile papilla. The duct of Santorini passed up from the lower part of the head in front of the duct of Wirsung, with which it com-municated by a large branch, and then curved round the left side of the sac, rising as it passed forwards to open into the duodenum above and to the left of the diverticular opening. An artery from the gastro-duo-denal artery dropped down to the wall of the sac and was distributed in several branches. In commenting on the absence of any satisfactory explanation of these diverticula, which are usually found in the situation described, the exhibitor suggested that in these diver-ticula we possibly had evidence of an effort of the duodenum to produce a gland—perhaps part of the pancreas, perhaps a gland that was neither pancreas

Professor Dixon and the President briefly discussed the communication, and, in reply to Dr. H. M. Johnston, Professor M'Loughlin stated that the wall of the sac was thin and composed chiefly of mucous membrane, but a ring of muscle was present around the circumference for a short distance up the wall.

LANTERN DEMONSTRATIONS OF SURFACE ANATOMY.

Professor Fraser gave a lantern demonstration of a series of slides, showing (a) the living model from the front, the back, and the side, with the superior extremity in various positions; ((b) a series of the head and neck, showing the various movements, flexion, extension, lateral inclination, and rotation to right and left; (c) a series of the trunk, showing its various movements—flexion, extension, lateral inclination, and rotation to right and left; (d) a series of the lower extremity, showing the various degrees of flexion from the outer and inner aspects of the limb.

The President and members expressed their appreciation of the beautiful series of photographs exhibited on

the screen.

THE LORD PRESIDENT OF THE COUNCIL has been pleased to appoint the Hon. Mrs. Charles Egerton to be a member of the Central Midwives Board in the place of Miss Jane Wilson, resigned.

GLASGOW EASTERN MEDICAL SOCIETY.

MEETING HELD FEBRUARY 3RD, 1909.

The President, Dr. J. W. MATHIE, in the Chair.

### CEREBRO-SPINAL MENINGITIS.

THE President, Dr. MATHIE, read notes of two interesting cases of cerebro-spinal meningitis, one that of a girl, the other of a woman, both of whom recovered. In the case of the girl, hearing was lost. An interesting discussion followed.

interesting discussion followed.

Dr. Granger stated he had attended 17 cases, with several recoveries. He had found deafness the most

common complication.

Dr. GLEN had had a case followed by hydrocephalus. Dr. MACLACHLAN said that cerebro-spinal meningitis was a disease very difficult to diagnose in the early stage, as it was apt to be mistaken for influenza or pneumonia. The severe headache and general malaise did not yield to salicylate of soda, as was generally the case with influenza attended by headache and myalgic pains. He had employed aconite successfully in two cases where the symptoms pointed to cerebrospinal meningitis. Two cases where a more or less expectant treatment had been adopted died within four days. Although aconite was not classified as an antiseptic, he had no doubt as to its power, when used early and vigorously, in diseases that undoubtedly were connected with germ life.

Dr. Peter Buchanan showed a woman whose fore-

Dr. Peter Buchanan showed a woman whose forearms were short and flail-like. At the right elbow-joint there was a considerable gap between the humerus and the bones of the forearm, while on the left arm the radius and ulna met the humerus obliquely one or two inches above the normal site. The inner condyles of the humeri appeared to be absent.

Dr. McKall showed a woman, æt. 63, with a rodent ulcer on the upper eyelid of the left eye. It was of two years 'standing. It was depressed in the centre, and had a hard-rolled edge. There was no pain; but it bled when the face was washed. It was about the size of a shilling.

### A CASE FOR DIAGNOSIS.

Dr. James Dunlop brought a man with an affection of the tongue for diagnosis. He was æt. 40, and had a somewhat clay-coloured complexion. There was a large, ragged, dirty-looking ulcer, foul smelling, on the dorsum of the tongue. It was very painful. It had begun as a small lump rather to the right of the middle line of the tongue, which the patient declared had broke two months ago. He had syphilis many years ago. There were a mass of glands under the sterno-cleido mastoid on either side of the neck, rather low down. The prevailing opinion was that it was syphilitic in origin; that a course of iodide of potash should be given. There was a large white patch of leuco-plakia on the tongue, and one or two speakers considered it was malignant in nature.

CLASGOW MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD IN THE FACULTY HALL, JAN. 22ND, 1909.

Dr. WALKER DOWNIE in the Chair.

Dr. Robert Muir, Professor of Pathology in the University of Glasgow, read a paper the subject of which was "A Consideration of Some of the More Recent Work on Immunity, especially in Relation to Diagnosis and Treatment."

A short discussion followed, and Dr. LINDSAY. STEVEN proposed a vote of thanks to Professor Muir for the interesting paper he had read before the Society, an abstract report of which will be found in another column, under the heading of "Original Papers."

By permission of the Lord Mayor of London, the annual meeting of the Royal Free Hospital will be held at the Mansion House on March roth next at 3 p.m., when the claims of the hospital for increased public support will be advocated.

THE SEMEIOLOGY OF PAIN.

PAIN, in a medical and philosophical point of view, is an interesting phenomenon, any definition of which would be useless as it is personally known to all; in any case, it is an experience that no one cares to recall.

Yet it is, says Dr. Legendre, one of the best agents of human progress; it is a useful phenomenon; it denounces conditions that might be hurtful and puts the

individual on his guard.

It is impossible to separate physical pain from moral pain. When an individual suffers from dental neuralgia, for instance, he not only experiences physical pain, but also a degree of impatience which, if prolonged, produces nervous prostration, rendering incapable of work or thought. If the affection is incurable, as sometimes happens, the mental condition becomes such as to lead the patient to the verge of suicide. On the other hand, moral suffering, as some acute disappointment, the loss of a loved one, produces physical sensations, general malaise, epigastric oppression, loss of appetite, insomnia, neurasthenia.

Acute pain lowers the temperature, and slight pain accelerates the beating of the heart, while excruciating pain produces syncope. Arterial tension is generally lowered if the pain is intense and prolonged, and the iris is dilated. The number of respiratory movements increases if the pain is moderate, if it is intense the respiration is slow, with a pause during the inspiration and expiration; where the expiration is prolonged, a groan is heard which is nothing else than a pro-longed expiration with contraction of the glottis.

In pain, the secretion of the gastic juice is suppressed, with loss of appetite and great thirst, explained by perspiration (cold sweats). Diarrhœa is frequently observed, and tears are the first results of acute pain in children and those who are of weak will

Pain differs in intensity, not only in different categories of individuals, but also at different periods of human life. The infant, for instance, would seem to suffer the least of all, in any case, the lachrymal secretion is not observed for several weeks after birth. In children, the most intelligent are the most sensitive, and girls more so than boys. Sensibility increases up to the age of 25, and then decreases gradually to old age. Aged people, as a fact, suffer much less than adults; hepatic colic, for instance, so painful in middle life, passes almost unnoticed in persons of advanced years; the pain is dull, vague and attenuated, so that error in diagnosis is frequent, and when jaundice sets in, the case is supposed to be one of cancer of the pancreas. Pneumonia in the adult sets in by violent pain in the side; in the aged, it begins insiduously. Woman seems more sensitive to pain than man, but she endures it better.

Professions exercise also an influence on the character of pain; persons of liberal professions suffer more acutely than workmen.

The races are also remarkable in this respect. Orientals, Egyptians, Arabs, Chinese, Japanese resist pain much better than Europeans.

Does pain result from excessive irritation of sensitive and sensorial nerves? Such was the conviction hitherto, but to-day there is a tendency to admit the existence of centres of pain and that of special nerves.

Pain produces pain; consequently, patients should be examined with gentleness, so as to cause the least suffering possible to the patient, and not to be hindered in the examination. The physician who increases the suffering of his patient places himself in an unfavourable position to make a good diagnosis.

It should be borne in mind, also, that inflamed tissues are particularly painful, and that tissues normally without much sensibility, as tendons, cartilages, periosteum, fibrous tissue, and such organs as the in-

testine, bladder, uterus, become very painful under the slightest congestive conditions; in certain affections-

phenomena occupy the foreground.

Certain pains return at a fixed hour, while others are particularly nocturnal. Night increases pain, perhaps chiefly in a moral point of view. During the day he mind of the patient is more or less diverted from his suffering; at night he is left alone with his thoughts.

Pain can be either persistent (migraine) or mittent (hepatic, nephritic, or intestinal colic). In inflamed tissues (phlegmon) the pain is pulsatile; other types of pain are lancinating, fulgurating (ataxy), terebrant (cancer of bone), burning (erysipelas).

Some pains are purely suggestive, and correspond with no precise morbid condition, while others are experienced at a distance from the affected region. In pericarditis, for instance, the pain felt in the epigastrium and between the insertions of the sterno-mastoid muscle, is characteristic. Pain in the right shoulder in disease of the liver, in the ear in tonsillitis, is well known. In consumptive persons, besides intercostal neuralgia, pain is frequently felt in the shoulder, the neck, wrist and fingers. Certain affections of the uterus provoke pain in the lumbar, abdominal, and inguinal regions; dysmenorrhæa is frequently accompanied with headache, disease of the bladder by pain in the glans, while the pain in the knee of coxalgia is known to all.

GASTRIC AND INTESTINAL HEMORRHAGE.

A tablespoonful every 2 hours.

GERMANY.

Berlin, Feb. 7th, 1909 At the Medical Society, Hr. Dührssen gave a demonstration of a new method of delivery, which consisted in the following —A metreurynteur is first introduced for the purpose of softening the parts. After this has been effected a vaginal Cæsarean section is made, and, following this again, the child is extracted through a lateral suprapubic incision. The procedure, complicated as it appears, is not so, but is simple, is free from danger, and allows of a really extra-peritoneal Cæsarean section. The speaker had employed it in one case, with the result that a living child was born, although the same woman had lost her two previous children inter partum. The patient made a good and easy recovery.

Hr. Solms had thought of the method, and had carried it out in one case, and recommended its employ-

ment in suitable cases.

Hr. Krömer objected to it as too complicated, and for that reason too dangerous. In place of it he recommended the procedure as carried out in Bumm's Klinik, which was to wait until the soft parts were dilated (the metreurynteur might be used for this if necessary), and then the extra-peritoneal Cæsarean section was performed, if required; otherwise hebosteotomy was done.

Hr. Dührssen, in reply, defended his own method, which he proposed to call "laparo-colpo-hysterotomy."

The Deutsche Med. Zeitung, 6/09, gives a brief account of a paper by Reg. U. Med. Rat Dr. Nesemann, of Berlin, on

THE HISTORY OF TYPHOID FEVER IN BERLIN.

The article deals with the history and the ætiology of the disease, and presents a striking picture of the evils of insanitary conditions and of the startling improvement that follows on practical attention to health requirements. The mortality statistics for the different years show, on the whole, a gradual decline. On two separate occasions a rapid fall took place—namely, in the years 1878 and 1894, on the first occasion from 612 in the previous year to 326, on the second from 143 to 67. The explanation of this lay in the sanitary work to 67. The explanation of this lay in the sanitary work that had been carried out in limiting or completely shutting off of river water, and replacing it with deep well water (Tegeler Werk).

writer's conclusions are as follows:-"The general high morbidity and mortality from typhoid fell at a time when the greatest insalubrity reigned, the soil and all the water-courses were fouled, the wells were a prey to all sorts of uncleanness, the central water supply not of the best, fæcal matter was but imperfectly removed, and in part was positively dangerous as regarded health. With the gradual improvement of these conditions, a gradual decrease of typhoid took place; the diminution was first noticeable in the streets that were sewered, probably for the reason that the soil became less saturated, and the water of the wells less contaminated.

A great and sudden fall both in morbidity and mortality was associated with a partial disuse of the highly objectionable river water, and again on its use being

given up altogether.

"For the preponderating dependence of the frequency of typhoid in a city on its water supply as compared with other factors, and especially its sewerage, the behaviour of the disease in Berlin affords a striking and instructive example."

ANTE-PARTUM BAPTISM. A paper by Dr. Treitner in the Theolog. Pract. Quartalschrift discusses this subject. The writer says that hitherto an attempt has been made to baptise the living fœtus in utero by means of the finger or with a syringe introduced into the uterine cavity. The objection to the first-named method is that the water is soon wiped off the finger as it is passed through the vagina, and before it reaches the fœtus at all; by the second method the membranes must be perforated. Then the syringe must be guided by the finger in order that the baptismal water may reach the child's head. There are

difficulties in the way of this when the os uteri is small,

and in the earlier months of pregnancy.

The writer, a practitioner of Innsbruck, therefore proposes the following method of procedure: A syringe is filled with the baptismal water; the syringe should not be disinfected with any disinfecting fluid, as some of this may get mixed with the baptismal water, whereby the latter would lose its efficacy. In case of a head presentation, the puncture is made above the symphysis, the syringe is passed in until it touches the head of the child. If nothing like the head is felt the instrument is withdrawn as far as the abdominal parietes, and a trial is made in another direction; the operator will not have to make more than three or four tries. If the mother is dying, so that she cannot be uncovered, the puncture must be made through the dress. In any case the puncture must be made with force, and the operator need not be afraid of penetrating the child's skull; it will do the child no harm; it is important, as the child's head may be covered with "Kindspech," and for this reason the baptismal water might run away from the child's head. (The con-tributor who is responsible for the insertion of this paragraph feels himself bound to add that it is not a sorry jest.)

# AUSTRIA. Vienna, Feb. 7th, 1909.

OUR PRESENT KNOWLEDGE OF CHOLERA.

AT the Gesellschaft, Kraus reviewed the present treatment and diagnosis of cholera, which, he thought, should be in the minds of every practitioner when the disease was so near. The recent cholera epidemic in Russia had given him many opportunities of testing the worth of many of the prescribed methods, but it is yet certain to the most casual observer that more must be learned of the cause before we can dogmatise on the treatment. It is still a difficult task to diagnose the vibriones, although it is confidently affirmed that hæmotoxin is diagnostic, but Kraus now assures us this is not the case, as we have invariably to fall back on Pfeiffer's biological test to distinguish the true cholera vibrio. Even this test does not distinguish the El Tor vibrio of the Arabians from the genuine Asiatic vibrio, which has been confirmed by Gottschlich, who examined the vibrio taken from the bowel of deceased Mecca pilgrims who did not die from cholera, but when it was cultivated and injected had all the characteristics. In this case the biological test is quite falla-

Notwithstanding these facts, we have high authority for believing that these vibriones have a choleraic nature and may transmit genuine cholera to a third party. Kraus next referred to his own experiments with the El Tor vibrio, which he cultivated and obtained the biological result and all the characteristics of cholera, even to the formation of hæmotoxins, and yet the cholera symptoms were not present. From this he concludes that the biological method is not reliable, as the El Tor vibrio can be cultivated for months, and even years, with the same constant result. Again, he gave a history of 23 cholera cases which he examined in the 1907 epidemic in Russia, where the vibrio produced no hamotoxin, which, according to the latest theory, would be regular. He concluded that the theory, would be regular. formation of hæmotoxin was not reliable, but was in favour of the "Blut Platten" method being the sovereign diagnostic sign of the disease. Where an epidemic was present the agglutination method would be handy and reliable in general practice.

We have now to consider an anti-toxin, but from

the number of the vibriones that so closely resemble the cholera germ we are at a loss to select a specific that will neutralise the genuine cholera toxin. vestigators have affirmed their successful treatment with a product of their own. As to whether these have any prophylactic or healing powers great doubt is enter-tained, but it is reasonable to believe that such exists, as injections of serum in mice and guinea-pigs have shown that the cholera vibrio can be resisted for a long time, if not altogether neutralised. The experiments at present give very little hope for success with any serum, although guinea-pigs have been found to remain immune for a long time. The tests in vitro give no more satisfaction than the biological.

In the recent Russian epidemic Kraus has used an anti-toxic serum which he obtained from the El Tor vibrio. He has injected 119 cases, in 70 per cent. were subcutaneous, and injections in 49 intravenous. Of the subcutaneous cases, 58 per cent. died, while the intravenous had a death-rate of 50.6 per cent., which may be compared with the total death-rate of untreated cases, which is 58.7 per cent. This makes very little difference from a statistical point of view, but when we consider that the doubtful or hopeless cases were only injected, the mortality shows a favourable reduction by the serum treatment. Early injection is another factor to be considered, as we know the antitoxin in diphtheria, when delayed three or four days, makes the results very doubtful. Hence early treatment, more particularly in cholera, must be recognised, and the best form intravenous with a solution of salt as the vehicle. Zeatogorow in 1904 vaccinated in North Persia with a serum whose results showed that the mortality was four times less in the vaccinated than in the non-vaccinated, while the attacks were five times less. Other authors in the same region give similar results.

# HUNGARY. Budapest, Feb. 7th, 1909.

HOSPITAL ABUSES IN BUDAPEST.

HOSPITAL abuse occurs in Budapest as in other large medical centres. The leading medical charities in Budapest are the Royal Policlinic, and the "Out-Patient Departments" of all the Clinics. Patients applying for advice or treatment at those institutions are asked to give their names, ages, occupations, and addresses, no further guarantee of fitness for receiving help from a charitable institution is required. Budapest, as in other large cities a large proportion of those benefiting are quite above the class that were originally intended to be beneficiaries. While the medical officers are fully conscious of the existing abuses, the general feeling amongst them is that it is not their part to take any action. It is, indeed, very questionable if it is in their power to do anything to improve matters, for questions as to wage earnings, etc., too often only elicit evasive or erroneous answers, and only trespass still further on the medical officers' time. Another way in which medical men in Budapest are exploited is by the numerous and, in some

cases, very large Friendly Clubs and Sick Clubs, so numerous and large indeed that their members compose a very considerable part of the community. These friendly clubs, etc., pay their medical men annually 4s. 2d. per member, 5s. if, in addition, the family of the said member is attended.

THE HEALTH OF SCHOOL CHILDREN,
The annual report of the Medical Officers of the
Budapest Municipal Schools states that a large number of the children suffered from general debility, scrofuof the children suffered from general debility, scrofulosis, and tuberculosis. Of 11,379 children for whom admission was sought, 334 had to be refused for general debility, 138 for scrofulosis, and 67 for tuberculosis of the lungs; at the same time 317 children suffering from general debility, 3 suffering from scrofulosis, 90 suffering from pulmonary tuberculosis were admitted which to their kept under medical cheeryties. subject to their being kept under medical observation. Of all the 91,384 children attending the municipal schools 1,347 suffered from imperfect nutrition, 519 from scrofulosis, and 417 from pulmonary tuberculosis; all these case were, accordingly, kept under medical observation. The report draws the attention of the school authorities to the great number of chil-dren who are insufficiently fed and suggests that this question might form the subject of a collective investi-The municipal authorities support milk and bread distributing institutions in every district of the

POTT'S DISEASE IN CHILDREN.

From an extensive study of the disease, as well as considerable experience in dealing with same, Dr. Alapy draws the following conclusions:—(1) Tuberculous spondylitis is pre-eminently a disease of the young child. (2) The greatest number of cases is found between the ages of 2 and 8 years. (3) In his hospital experience the author met a greater number of girls than of boys, the number of the former being almost double that of the latter. (4) The duration of the disease before the admission to the hospital was between a few weeks and one year. (5) In the presence of undoubted predisposition, whether because of heredity or on account of surrounding conditions of life, measles and at times trauma may serve as the startingpoint of the disease. The complication of spondylitis by measles shows itself very rapidly in deterioration of the patient's condition. (6) The lumps were mostly found in the thoracic portion of the spine; the lower thoracic vertebræ were usually the most affected, and the curvature was generally limited either to these vertebræ or to the upper lumbar. (7) With the evacuation of the abscesses, followed by filling up of the cavities with a 10 per cent. solution of iodoform emulsion, or after a curettage done with the same aim in view, followed by a hermetic closure of the opened abscess, satisfactory improvement would be observed in those localities where the skin has not grown too thin. (8) Cases of active surgical interference and further treatment with drainage also showed a considerable degree of improvement, though the most frequent post-operative complication was usually a febrile condition. (9) Correct methodical extension and counter-extension in bed often, in combination with suspension with the Sayre apparatus, are to be considered as the best means in the majority of cases of checking the development of the tuberculous process, and of creating favourable conditions for the further treatment with corsets. (10) Besides the specific treatment, it is absolutely necessary that resort be had to favourable climatic surroundings, as in special sanatoria at the sea shore or on the mountains, but never in hospital. (11) Out of six who died, four were found to have suffered from pulmonary tuberculosis, and two had, in addition, fatty degeneration of the heart.

# SCOTLAND.

ABERDEEN ROYAL INFIRMARY.-The directors of the Aberdeen Infirmary propose to enlarge the institution by erecting three new operating theatres, with the usual annexes, by rebuilding the out-patient

department, by reconstructing the basement of the surgical block and adapting the space for electrical work. They also intend to improve the premises occupied by the gynæcological and ophthalmic departments, and to provide better rooms for the resident medical and nursing staffs. A number of other minor alterations are contemplated, and the effect of the whole will be greatly to improve the Infirmary and extend its power for good. The expense which the changes will involve is defrayed by the generous gift of £26,758 received last May from Lord Mount-Stephen.

EDINBURGH UNIVERSITY.—Professor Chiene has been granted leave of absence for three months on account of ill-health. Mr. David Wallace, C.M.G., acts as his substitute in the course of Systematic Lectures, and Mr. Alexis Thomson has been appointed to the charge of the wards in the Royal Infirmary during his absence. Prof. F. M. Caird was entertained as the guest of the Cap and Gown Club on January 30th, on his elevation to the Chair of Clinical Surgery. The Cap and Gown Club is a very popular social club in Edinburgh, and

Mr. Caird is one of its oldest members.

THE LATE DR. ARGYLL ROBERTSON.—According to newspaper reports which have arrived from India, the body of the late Dr. Argyll Robertson was cremated in accordance with his expressed desire. The ceremony was deeply impressive. The funeral service was read by the Rev. G. S. Stevenson, and the pyre on the banks of the River Gondli was lit by the Makore Sahib of Gondal, himself a medical man, an Edinburgh graduate, and a Fellow of the Royal College of Physicians of Edinburgh. In performing this last tribute of respect to the dead, the Makore Sahib broke through the ancient customs of his race, for it is contrary to all usage for a Hindu Rajah to take part in a funeral procession, or to wear a white or black turban as mourning. Hindus and Mussulmans united in closing their shops out of respect to the deceased, and sent a message of condolence to Mrs. Robertson.

FIRE AT THE GLASGOW ROYAL INFIRMARY.—Considerable alarm was caused at the Royal Infirmary on Saturday night by a fire which broke out in the dome. The fire brigade were soon on the spot, and succeeded in getting the outbreak under control. Owing to large quantities of water descending from the dome into the ward beneath, 40 patients were removed to another part of the building. There was great excitement outside the building, but inside everything was quiet and orderly. Damage to the extent of about £1,000 was done. The dome in which the outbreak occurred was over the original building.

#### BELFAST

Women's Health Association.—The first annual meeting of the Lurgan Branch of this Association was held last week, and was most cordially supported by the local medical men. Among those who took part were Drs. Deeny, Darling, Bracken, Agnew, Pedlow, and Mrs. Haire, M.B. The committee reported that attention had been given to the subject of cookery teaching, and few medical men will find fault with their statement that both national health and temperance will be promoted by instruction in cookery and domestic hygiene. Arrangements have been made for a course of lectures on hygiene and the care of infants and school children, to be given by Dr. Marion Andrews, of Belfast. After the business part of the meeting, Professor Symmers delivered a most interesting lecture on " Some Modern Views as to the Cause of Disease."

METHYLATED SPIRIT IN LINIMENT .- An interesting case was heard at Bailieborough (Co. Cavan) Quarter Sessions before his Honour Judge Drummond. local chemist had been summoned for using methylated spirit in the preparation of iodine liniment, instead of pure, duty-paid spirit. The magistrates had dismissed the case, and the Inland Revenue authorities appealed. It was said that the methlyated spirit cost 2s. 6d. per gallon, and the pure spirit would have cost 25s. to 3os. per gallon. It was submitted that there was no case against the defendant. The liniment was in constant use as a cattle rub, and was never intended or prepared for human or internal use. His Honour said: "I consider this a scandalous case. It should not be decided here. This defendant uses a condemned drug because he can make a huge profit out of it, and the public are to be poisoned and cheated for his profit. The case should not be decided here. It is of too great public importance. I will state a case for the Superior Court if Mr. Cochrane asks me. I regard the case as one of the greatest importance."

Down District Lunatic Asylum.—Sir G. P. O'Farrell, who inspected this asylum lately, calls special attention in his report to the way in which clinical notes and histories of all cases are being kept by Dr. Nolan and his assistants. All the 751 cases on the register are kept in two volumes, one for males and one for females, by a new system, the "Kalamazoo." The printed headings of the new case records have been drawn up by Dr. Nolan on the lines of modern scientific requirements, and the assistant medical officers deserve praise, says the inspector, for the careful manner in which these records are kept.

# LETTERS TO THE EDITOR.

ONE MORE CAUSE OF THE SPREAD OF TUBER-CULOSIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—The sensible letter by Dr. Hodgson in your last issue has much to commend it. The ordinary feather pillow (more especially in hot weather) is execrable; one side of head roasted, the other exposed to any current of air circulating in sleeping apartment. The emanation from warm feathers is not healthy, to say the least; many prefer a horsehair pillow for this reason. I see that a hygienic pillow is now on the market, made by Messrs. Bailey and Son, Rathbone Place, which admits a free current of air under the head of the sleeper, and this should get over a good many of the objections urged against the usual form of pillow. I can imagine one of the reasons for insomnia so common nowadays is too much heat to the head, and this would also account for the change of position during sleeping hours, very few when waking finding the head in the position chosen when waiting for "Nature's sweet restorer."

I am, Sir, yours truly,
ALEXANDER DUKE.

London, W., February 5th.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is being gradually but surely brought to my understanding that the "peace of mind" I had fondly hoped for in my declining years, will not outlive many days with the rapid march of science, which even many of my poorer patients know more about than some of us who boast of University honours. In the midst of my reverie as to whether I ought not to renounce fish, flesh and fowl and become a vegetarian as the summum bonum of mundane existence, I was startled with the recently discovered knowledge that even those apparently innocent products of Nature's womb—vegetables and fruits—often swarm with microbes, and that if I dare to pick a rose in my back garden, I run the risk of septic infection from the prick of a thorn.

A week ago your contemporary the Lancet had a serious article on the sorrows attending golf, a game I indulge in, when I can get away from a strenuous practice; and later still, I am warned in my favourite journal (MEDICAL PRESS AND CIRCULAR, Feb. 3rd) by my friend Dr. Hodgson that it is dangerous to lay my head on an unsterilised pillow, lest I inhale "the swarms of germs" breathed into that same pillow by the previous occupant of the bed. It is plain, on the authority of the Lancet, that I must give up golf, although I had stupidly imagined I felt better for the game. But what am I to do with my pillow? At home this will be all right, as I can lock it up with the silver in the safe when leaving; the difficulty will arise when sleeping at the house of a friend, or at an hote!. To the managers of the latter, I would suggest

a notice in the bedrooms, "Pillows baked every morning." Such caravanseric I will patronise in due time when the practice has been perfected. Till then I shall stay at home and stick to my one pillow.

I am, Sir, yours truly,
February 5th, 1909. MUCH WORRIED.

THE OFFICIAL MEDICAL REGISTER—IMPORTANT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—A very searching inquiry is now being made as to the accuracy of all names and addresses on the Medical Register under the following Section (XIV.) of the Medical Act, 1858:—

XIV. It shall be the duty of the Registrars to keep their respective Registers correct in accordance with the provisions of this Act, and the Orders and Regulations of the General Council, and to erase the Names of all registered Persons who shall have died, and shall from time to time make the necessary alterations in the addresses or qualifications of the persons registered under this Act; and to enable the respective Registrars duly to fulfil the duties imposed upon them, it shall be lawful for the Registrar to write a letter to any registered person, addressed to him according to his address on the Register, to inquire whether he has ceased to practise, or has changed his residence, and if no answer shall be returned to such letter within the period of six months from the sending of the letter, it shall be lawful to erase the name of such person from the Register; provided always that the same may be restored by direction of the General Council should the; think fit to make an order to that effect.

On February 1st a circular of inquiry was posted to every registered practitioner, excepting only officers of the Navy, Army, and Indian Medical Services whose names appear in the Navy and Army Lists.

It is of vital importance to all registered practitioners who have not received an inquiry in course of post that they should immediately communicate with this office, as, in the event of no communication being received from them, it will be lawful to erase their names from the Register, according to the Act, and then very serious disabilities will be incurred.

I am, Sir, yours truly,
H. E. ALLEN, Registrar.
General Council of Medical Education and
Registration.

299, Oxford Street, London, W., Feb. 3rd, 1909.

#### MEDICAL MEN IN PARLIAMENT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—You draw attention in your last issue to a grave disability under which we, as medical men, suffer, in not being properly represented in Parliament. Year after year legislation is introduced placing additional burdens on our shoulders, burdens we are expected to bear cheerfully for the good of the State, without any other reward for the work. We never hear of such demands being made from solicitors or barristers, for the simple reason that personally they are well represented in Parliament, and that outside Parliament their interests are properly protected by the Law Society and the various Inns of Court. We, however, are almost without a voice in Parliament, and our corporations and associations are ineffectual or careless.

While recognising that the good offices of the medical men in Parliament are for the most part at the service of their fellows, it is important to remember that unless elected as university members, they have no responsibility to the profession. Moreover, they may not be fitted to speak with authority for the profession, their eminence being rather political than professional. If these men chance to be anti-vaccinationist, anti-vivisectionist, or cranky in other particulars regarding science or health, their position as members

of Parliament makes their opinions a hundredfold more dangerous. They are regarded, in fact, as voicing the opinion of a section at least of the profession, while merely uttering their own cranky notions. The presence of such people in Parliament is a danger, and medical men would be better without them. On the other hand, medical men who are eminent as politicians are not unlikely to be nonentities in a professional respect, and their utterances on medical subjects tend to make us ridiculous. Unless, therefore, we can be represented by the right sort of men, I believe we are better without medical men at all in the House. Under present conditions, the Universities seem to be the only constituencies which can return suitable medical members, and medical electors should do their best to find and support suitable candidates for the Universities. In the failure of medical candidates, we should also do our best to make sure that other candidates are sound on such subjects as vaccination and experiments on animals.

I am, Sir, yours truly, CRITICUS, M.D.

# PURULENT CONJUNCTIVITIS OF INFANCY. To the Editor of The Medical Press and Circular.

SIR,-I see that the Council of the Association have appointed a sub-committee, under the name of "Ophthalmia Neonatorum," to inquire into the incidence of the purulent conjunctivitis of infancy. strongly suggest that the first matter to which that sub-committee should address its attention is that of assigning to the disease the name which correctly describes it. The term "ophthalmia" owes its origin to ignorance. In these days it implies nothing. For ages, through ignorance, it was appended to many diseases of the eye, such as rheumatic ophthalmia, arthritic cphthalmia, gonorrhoeal ophthalmia, "strumous" ophthalmia. All these expressions have, with increased knowledge, passed out of use, and to the diseases in question the correct definition has been given. The continued use of the word "ophthalmia" as applied to the conjunctivitis of infancy is, I contend, largely answerable for the neglect and want of due recognition of the disease in the past, into which matters the sub-committee have been appointed to inquire. Upon the term has been built a superstructure of mystery and misconception which has traditionally misled practitioners, midwives, and nurses into ignoring the true significance of the disease, and into believing that such cases, when they occurred, could be generically regarded as "only a little ophthalmia." What wonder, then, that so much blindness has resulted from the disease, under these circumstances? What wonder that practitioners should continue to overlook such cases, and midwives to persist in treating them with milk and cold tea until the vision has been permanently destroyed? Again I say, how can this be otherwise, as long as most ophthalmic surgeons, simply for the reason of paying tribute to that oftentimes irrational reason of paying thouse to that the term in although the term "ophthalmia" conveys. It has been held by some that the term is useful, as indicating a "generic" condition of conjunctival inflammation. I cannot conceive of a contention more inane than this. Just as well, for example, might it be argued that the old time expression "perityphlitis" should be retained to describe an attack of appendicitis. It is, however, of little avail, the present generation clinging tenaciously to the term "ophthalmia," for which, apparently, so much affection is displayed. In the next generation the word will have passed into that oblivion which constitutes the fate of all ignorance which knowledge has displaced.

But there is another aspect from which this question can be viewed. I allude to the complexity, the multitudinous variety of methods of treatment of cases of purulent conjunctivitis of infants. If in this day the question were categorically asked, "What is the expert treatment of this disease?" the answer can only be, "Oh, some ophthalmic surgeons use this 'ol,' some that 'ol,' some silver nitrate, some mercury perchloride. some repeatedly deluge the conjunctival sac with pints of potassium permanganate, and some resort to methods

of their own which do not see the light of publication." Amid such therapeutic chaos and unnecessary confusion, it is evident that the bad impression thus created by these diverse opinions could not fail to react harmfully upon the minds of those to whom the cases first come for treatment. Apart, however, from the conclusions at which the sub-committee upon the purulent conjunctivitis of infants may happen to arrive, we must still regard the matter, not merely as a national, but as a racial one—that is, which affects humanity at large. Well, therefore, would it be if at the forthcoming meeting of the International Ophthalmological Congress, a sub-committee were to be appointed, to agree, first, upon the proper terminology of the disease, and, secondly, to draw up a definite schedule of treatment which would serve as an authoritative expression of opinion, to be incorporated in all future text-books, and to be regarded as the standard loyally adopted and advocated by ophthalmic surgeons throughout the world. This would constitute the first definite step in the organisation of a system designed for the purpose of checking the ravages of this fateful On the other hand, it is impossible to anticipate beneficial results from any action which may be taken in this regard until the matter has been placed upon the firm basis of organisation.

Lastly, so far as the suggestion is concerned of attempting to secure legislation for the betterment of the present deplorable results of the purulent conjunctivitis of infancy—to that I am opposed. Legislation may in the future prove to be necessary, but its advocacy at the present moment is certainly premature. To the common-sense legislator the ordinary question would first suggest itself, "Have ophthalmic surgeons exhausted the means at their command to guide the profession and others concerned towards the proper realisation of the significance of the disease, its prevention and treatment?" I, as an ophthalmic surgeon, feel bound to submit that the answer must be in the negative, and partly for the reasons which I have indicated above.

dicated above.

I am, Sir, yours truly,

PERCY DUNN.

Wimpole Street, London, W.

# TESTING DISINFECTANTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Anent Mr. Walker's letter in your issue of January 27th, it seems to me that his methods in controversy are no sounder than his practice in the art of testing disinfectants, and that, directly his methods are exposed, he complains of personalities and charges his critics with "deliberate attempts to distort facts," whereas his own methods have very properly brought the criticism upon his head.

He has applied the Rideal-Walker test to various disinfectants, and published results, the accuracy of which has been disputed; he has compared various preparations by this test which should not have been compared with each other under the conditions imposed by him, and in some instances he has applied the test to certain sanitary preparations to which it is not properly applicable, apparently for the sake of unduly appraising his own company's manufactures at the expense of others, rather than by way of an "honest attempt to grapple with a serious and difficult problem in a scientific manner."

In a scientific manner."

In substantiation of my charge, I may recall my challenge of the accuracy of his examination of "Sanitas-Okol," which I backed by a financial consideration in aid of the King's Hospital Fund, which he shirked (Sanitary Record, Sept. 26th, 1907), and I may remind your readers that he has never compared other manufacturers' disinfectants of the coal tar order with Jeyes' Fluid—an article of his company's manufacture labelled poison, which is extensively advertised to the public, and which, with a co-efficiency of 2½ by the said test, has been sold for years past without any guarantee of co-efficiency—but always with "Cyllin," which, although advertised to the medical profession, is little known to the public at large.

is little known to the public at large.

As to the final part of my charge, it is well-known and recognised by chemists that the Rideal-Walker test is applicable to but few other than coal tar disin-

fectants, and Mr. Walker has again and again issued reports giving the results of the test as applied to other preparations, the disinfectant value of which cannot possibly be gauged by it, always again in comparison with "Cyllin"—a preparation which is amenable to the

The Rideal-Walker test has a value, of great limitations, but it is perfectly useless for determining the value of many disinfectants which are quite as serviceable as coal tar preparations, or more so. Mr. Walker should know this perfectly well, if he bases his claims for personal consideration upon a knowledge of chemical as well as bacteriological science.

As for the alleged common hospital practice of allowing a mixture of emulsified disinfectant with water to stand 24 hours before use, if it be true—as I fear it is-it is, all the same to be lamented, for all such mixtures, so far as they are used at all, should

be freshly mixed each day.

To exemplify the misleading nature of the Rideal-Walker test as often applied in practice, it will suffice to give an instance. Dr. W. C. Hossack, District Medical Officer of Calcutta, has found by a series of medical Omeer of Calcutta, has found by a series of carefully conducted experiments that one of the cheapest disinfectants manufactured by this company, viz., "Sanitas Soluble Fluid, B quality," having a coefficient of about 2, as determined by this test, is much more efficacious as a pulicide (for destroying fleas on rats) than "Cyllin," with a co-efficient of, say, 15. Here is an instance of one application of a disinfectant that cannot be gauged at all by the Rideal-Walker test.

As further instances, it may be mentioned that the disinfectant values of the following substances cannot districtant values of the following substances cannot be determined by this test—viz., chlorine preparations, sulphurous anhydride, formaldehyde, manganates and permanganates, peroxide of hydrogen and its compounds, such as "Sanitas Fluid." I particularly emphasise peroxide of hydrogen because it is one of the most serviceable disinfectants, even in dilute solutions, for dressing wounds and suppurating tracts, etc.; and yet, when tested by the Rideal-Walker method, it would appear to have very little value, as ascertained by a number of experiments made in my own laboratory.

Again, it is easy to show by the test under discussion that a disinfectant, which we may call A, may have a higher co-efficient than another one, B, but it is quite possible that B may, all the same, be preferable for certain purposes. Further, all such strong germicides have to be mixed with large quantities of water before use, and the selling price of B, which is under the control of its makers and not of the makers of A, may be such that it is much cheaper to use, even if not better than A from other points of view. In any case the makers of A have no right to damage the reputation of B by making and publishing any such comparisons as those, the subject of complaint.

Summing up the situation, it seems to me that the Rideal-Walker test, as applied by Mr. Walker, has proved very much more harmful than useful. All comparisons of the kind he has made are odious, and as there is plenty of scope for scientific progress and reward in the preparation of disinfectants and sanitary appliances without decrying one's neighbour's goods, Mr. Walker would be well advised by abstaining in future from a practice which is unfair to his competitors in business, misleading to the medical profession and public, and certainly not in keeping with the best English traditions of fair trading.

I am, Sir, yours truly,
C. T. KINGZETT, Chairman,
(for the "Sanitas" Co., Ltd.).

# OBITUARY.

GEORGE EASTES, M.B.LOND., F.R.C.S.ENG., L.R.C.P.

WE regret to announce the death of Mr. George Eastes, at the age of 67, at his residence in Paddington, London. At the annual election of Fellows to the Council of the Royal College of Surgeons, in July last, Dr. Eastes was the selected candidate to represent the general medical practitioners of London, and the result of the poll showed him to have been only 11 votes

behind the last of the four successful candidates. He was a regular contributor to medical journals, and wrote many articles of interest to non-medical readers concerning vaccination and physical recreation. Eastes was educated in Paris, and pursued his medical studies at Guy's Hospital, where for two years he held the posts of house-surgeon, surgeon-registrar, and tutor. He was treasurer of the Metropolitan Counties' branch, and member of the Council of the British Medical Association, a past-President of the Harveian Society, a Fellow of the Royal Society of Medicine, and for fourteen years was chloroformist to the Great Northern Hospital. Dr. Eastes' qualifications included: Fellow of the Royal College of Surgeons, Bachelor of Medicine of the University of London, and Licentiate of the Royal College of Physicians. He leaves one son, the well-known pathologist.

# SURGEON-MAJOR T. J. TUCKER.

SURGEON-MAJOR THOMAS JOHN TUCKER, who died on January 27th, at his residence, Dean House, Hindon, was a veteran of the Indian Mutiny. Born in 1828, he entered the Army as an assistant-surgeon in July, 1855, entered the Army as an assistant-surgeon in July, 1655, serving in the 31st Regiment. He was present when three native regiments mutinied at Dinapur on July 25th, 1857, and at the defeat of the rebels under Koer Singh with the capture of Jugdespur in the following August. In February and March, 1858, he took part in the advance to Lucknow, and was present at the actions at Chanda, Umeerpur, Sultanpur, and Duraha, and at the siege and capture of Lucknow. For his services he received the Mutiny medal and clasp. In November, 1869, he became surgeon of the regiment, and in May, 1877, retired.

#### FRANK UTTEN PURCHAS, M.B., C.M.EDIN.

WE regret to record the death of Dr. F. U. Purchas, of Newton, which took place at the age of 48. He was born in Dry Harbour, Jamaica, and, coming to England for his education, determined to enter the medical profession. He studied at Edinburgh University, where he graduated in 1887. In 1888 he went to Newtown as assistant, and later became a partner with Dr. F. Ferguson. Some years after this Dr. Purchas acquired the entire practice, and afterwards took into acquired the entire practice, and afterwards took into partnership Dr. Shearer. Amongst the public appointments held by Dr. Purchas may be mentioned senior medical officer to the Montgomeryshire Infirmary, certifying surgeon under the Factory Acts, parish medical officer for Bettws and Llanllwchaiarn, and medical officer for the post-office. He leaves a widow and one daughter.

GEORGE WATT, M.D.ABERD., J.P. WE regret to announce the death of Dr. George Watt, of Aberdeen. Dr. Watt, who was 61 years of age, was a native of Donside, and came to Aberdeen in the late 'sixties. He entered Marischal College as a medical student, and graduated M.D. in 1876. He left Aberdeen for Loftus, Yorkshire, where he remained four years. In 1880 he returned to Aberdeen, and settled down to the practice of his profession. For many years he was on the staff of the Dispensary; he was medical officer for Blairs College and Nazareth House; sole referee in the Aberdeen district for the Prudential Assurance Company; and he was also medical officer for a number of industrial societies. An ex-President of the Aberdeen Medico-Chirurgical Society, he continued until the last to take an interest in its work, and he was the treasurer of the Widows' Fund of that society, and even in his weakness he would not be relieved of the duties of that office, so much did he like the work. He was a J.P. of the city. Dr. Watt was a man of unassuming and peace-loving disposition, and by his professional brethren he was held in the highest esteem, and they ever looked upon him as a man incapable of exciting ill-feeling or jealousy.

PROF. HENRY E. CLARK, F.R.C.S.Ed., of Glasgow. The death of Mr. Henry E. Clark will be deplored by medical graduates of Anderson's College and St. Mungo's College all over the world, where he laboured

so conscientiously as Professor of Anatomy and Surgery for many years. Being a splendid anatomist, he was a fearless and bold operator. He never got into a muddle or lost his head. He successfully removed the arm and scapula for a large sarcoma on the shoulder. He was particularly successful with cases of excision of the rectum for cancer. He never failed to interest and amuse, as well as to instruct his students, as he was amuse, as well as to instruct his students, as he was brimful of good humour and capital stories. He was a man of most exemplary character, abstemious, prompt, and punctual, and duty-loving. Being an omnivorous reader, he was buoyant in mind to the last, and could lift his mind from grave to gay in an instant. His memory will be long cherished, and will be associated with that of a brave surgeon and a good man. His name came specially into prominence at the time of the South African War in connection with the Scottish National Red Cross Hospital, of which he was placed in charge. On his return to this country he received the C.M.G. in recognition of his work at Kroonstad.

# SPECIAL ARTICLES.

## THE HEALTH OF THE NAVY

THE Report on the Health of the Navy for 1907 (a) is a much smaller volume than we have been accustomed to in previous years. Thus it contains only 108 pages and costs 7d., as against the Report for 1904, which contained 197 rages and cost is 11d. The information given is of a scanty nature, and the Scientific Appendix contains only two brief notes, one by Staff-Surgeon Whiteside on the work of the Royal Naval Hospital, Malta, and the other by Staff-Surgeon Rees on Air in Double Bottoms of Iron Ships. In former Reports we had perhaps ten or twelve papers, many of them of real scientific value. Of course, it may be admitted that a Blue Book is not a good medium for the publication of scientific papers, but we hope that the docking of the Blue Book of this feature only means that some other channel of publication has been

found for the work of naval surgeons.

We are glad to note that the classification of diseases has been made to comply with the 1906 edition

of the "Nomenclature of Diseases."

The returns for the total force for the year 1907 show an improvement on the Report of the previous year, the average loss of service for each person having

dropped to 10.46 days.

The total force, corrected for time, in the year 1907, was 108,740, and the total number of cases of disease and injury entered on the sick list was 75,351, which is in the ratio of 692.94 per 1,000, showing a decrease of 85.23 per 1,000, as compared with the average ratio of 85.23 per 1,000, as compared with the average ratio of the last 5 years. The number of entries per man for disease and injuries was:—On the Home Station, .66; Channel, .57; Atlantic, .66; Mediterranean, .68; North America and West Indies with Fourth Cruiser Squadron, .96; China, .98; East Indies, 1.03; Australia, .85; Cape of Good Hope, .71; and Irregular List, .97. For the total force the average is .69, a fractional decrease on the previous year's figures. The fractional decrease on the previous year's figures. The average number of men sick daily was 3,118.4, giving a ratio of 28.67 per 1,000, a decrease of 3.52 per 1,000 in comparison with the last 5 years' ratio.

The total number of deaths was 365, giving a ratio

of 3.35 per 1,000, showing a decrease of 1.05 in comparison with the average ratio for the last 5 years. Of this number 246, or 2.26 per 1,000, were due to disease, and 119, a ratio of 1.09 per 1,000, to injury.

Of the principal diseases recorded, we find that there were 2,501 cases of influenza; 166 of enteric fever, with 24 deaths; 441 of pneumonia, with 31 deaths; 371 of malaria, with 1 death; 305 of tuberculosis, with 30 deaths; 13,522 of venereal diseases, with 8 deaths; 849 of nervous diseases, with 9 deaths; 618 of diseases of the circulatory system, with 43 deaths; 7,179 of respiratory diseases, with 13 deaths; 11,010 of diseases of the digestive system, with 27 deaths; 19 cases of suicide occurred. Including these, there were in all 116 deaths by violence. Of Malta fever 29 cases are

(a) Navy (Health). Statistical Report of the Health of the Navy or the Year, 1907. London: H.M. Stationery Office. 296. Price 7d.

recorded, with 5 final invalidings and 2 deaths. In comparison with the average ratios for the last 5 years, the case ratio has fallen from 3.47 per 1,000 to .26, the final invaliding from .13 to .04 per 1,000; and the death from .06 to .01. Of malarial fevers, 371 cases are returned, with 1 death. The case ratio under this heading was 3.41 per 1,000, in comparison with 6.71, the average ratio for the last 5 years. This reduction is greatly due to the withdrawal of ships from malarial districts on foreign stations, but partly also to the careful use of mosquito curtains, and of quinine as a prophylactic by ships serving in such districts. Of venereal diseases, the total number of cases recorded is 13,522—viz., chancroid, 1,905; syphilis primary, 1,461; syphilis secondary, 3,215; gonorrhœa and its sequelæ, 6,941 cases. The final invalidings were: syphilis secondary, 163; gonorrhœa and its sequelæ. 50. Syphilis secondary gave 6, and sequelæ of gonorrhœa 2 deaths. The total number of days' loss of service was 329,936, while the average daily number from interfective from these discourse value. of men ineffective from these diseases was 903 9. The case ratio shows a decrease of 1.58 per 1,000, and the ratio per 1,000 of men daily ineffective shows a fractional decrease, in comparison with the average ratios for the last 5 years. Australia again shows the highest case ratio.

# REVIEWS OF BOOKS.

THE PUBLIC HEALTH ACT. (a)

This book (a), of 385 pages, containing much valuable information, is arranged in four divisions:—
I.—An Introduction (67 pp.). II.—The Public Health Acts Amendment Act, 1907, with Notes (151 pp.). III.—A Summary of recent decisions and Appendix, containing Sections of the Public Health (Ireland) Acts, 1878 and 1896, referred to in the Act of 1907, and the Notes thereto; the Prevention of Infectious Diseases Act, 1890; and the General Dealers (Ireland)

Act, 1903 (65 pp.). IV.—An Index (102 pp.).
For the non-legal reader the Introduction is the most interesting portion of the book, as it clearly and concisely summarises and explains each of the ten parts into which this, much the longest of the Acts amending the Public Health Acts, has been divided. authors are so anxious to emphasise the fact that, none of the provisions of the Act save Part I. take effect in any district till they have been applied by the Local Government Board or Chief Secretary, while they deal with each section as if it was in force, that they reiterate the statement on pages 3, 5, and 6. In Part I. the procedure for the application of the Act, or part of it, in a district, and in Part II. the Regulations for buildings and streets are explained. Part III. is concerned with more strictly sanitary matters, such as nuisances, drains, sinks, water-closets, urinals, public conveniences, and ambulances, and the provisions of the Act under each heading is fully discussed. Attention is called to a curious omission in the Act, that, while the local authority may contribute to the, or pay the entire, cost of altering unsatisfactory closets in existing buildings, that power is not extended to providing closets in buildings where there are none.

The arrangement of the sections of the Act in Part IV. dealing with infectious diseases is very hap-hazard; they are therefore re-arranged for consideration under the headings of (a) Control conduct, both general and in relation to common sources of infection; and (b) direct action by the local authority. Under (a) come exposure of persons suffering from infectious disease,

dairies, laundries, schools, libraries, etc.

With regard to schools, the writers point out that
Section 57 of the present Act, although it may be
applied to Ireland, is designed to introduce provisions against sending infected children to school, similar to those in our Public Health Act, into England. It is well to note that under the Act the medical officer of the district is to give certificates free of charge. Under (b) is included the cleansing or disinfection of

<sup>(</sup>a) "The Public Health Acts Amendment Act, 1907." By Arthur E. Clery, LL.B., and J. C. McWalter, M.A., M.D., D.P.H. Dublin: Edward Ponsonby. 1908. Price 2s.

infected premises, the removal of persons from unfilthy articles, and the cleansing and disinfecting of healthy houses, the removal of infectious patients to,

and the provision of, hospitals.

In Parts V. to X. the sections of the Act concerning lodging houses, recreation grounds, police and traffic, trades, servants' registries, marine dealers, sky signs, fire brigades, bathing, pleasure boats and boatmen—subjects rather outside the scope of Public Health are dealt with.

The Act itself is fully annotated, and cross references are made in both the Introduction and in the

portion devoted to the Acts.

There are a few repetitions which might well have been omitted—for example, those we have before referred to; the removal of persons, on page 44, which is treated of in a paragraph below on the same page; and the schedule of references to the Public Health

(Ireland) Act, 1878, which is printed twice.

The work has been well done. A great amount of important matter has been adequately and intelligently treated in an understandable way, in a small volume, which will be found of service to, and should be in the hands of all, medical officers of health and sani-

tary authorities.

## FIRST LINES IN DISPENSING. (a)

This small work is intended to serve as an introduction to the art of dispensing for students and nurses. Students, especially, have little or no idea as to how to make pills, ointments and other pharma-cal preparations. The result is that they are unable to write prescriptions, the ingredients of which are compatible. We are strongly of opinion that it would be an excellent thing if every medical student were examined in practical pharmacy during his final year. At all events more attention should be paid year. At all events, more attention should be paid to the subject during the ordinary curriculum. This volume contains all that the average student or medical practitioner needs to know on the subject. We notice that Mr. Lucas advocates the use of a porcelain capsule for the preparation of suppositories, and this we find is a very simple method and works well in practice. At the same time many examiners insist on the use of a water bath. Consequently we advise that in future editions a full account of this mode of manufacture should be inserted. At present mention is merely made of the use of a water bath for this purpose.

A very good account is given of the mode of pre-paration of so-called "percentage solutions," which often give the student considerable trouble. Although the work is stated in the preface to be merely an "introduction to the subject" of which it treats, we feel certain that it is just the sort of text-book to recommend to students of medicine. A careful study of its pages will lay a solid foundation for practical The teaching is sound, and the explanations given of the various manipulations are always clear and practical. The book is copiously illustrated, and contains a short appendix on poisons and their anti-

# ROTUNDA MIDWIFERY FOR NURSES AND

MIDWIVES. (b)

This small book, which Dr. Wrench has published with the object of simplifying the studies of nurses and midwives, is decidedly good. The teaching of the book is that of the Rotunda Hospital, and the author has considered his subject with the rules and regulations of the Central Midwives' Board always in view, so as to define carefully what treatment is within view, so as to define carefully what treatment is withing the scope of a midwife, and to point out when medical aid is to be sent for; thus, midwives who follow the advice given by the author will avoid contravening the regulations and endangering their own licence to prac-tice either through ignorance of the limitations put upon the duties of midwives, or through over-zeal and

a desire to retain the entire management of a case in their own hands.

There are a few minor points in the book which are open to criticism. The position in transverse presenta-tion is defined by the direction of the back alone; this does not convey much information unless the position of the head is also mentioned. In the methods of saving the perinæum no reference is made to the use of the right hand; its position is shown in the illustration, but the text does not say what it is there for. How to fit the binder does not conform with the method of the Rotunda unless this has been changed very recently; the chief point was the fixing of the third pin above the fundus of the uterus when it is contracted.

Another important omission is the second ligature applied to the cord at the time the baby is being bathed, which is always adopted in the Rotunda as a necessary and excellent precaution, especially in a visiting case. Complete and incomplete breech are reversed in the description of the presentation, and the illustration follows in the error.

The description of how to bring down extended arms might be fuller, as the complication must be dealt with promptly by the nurse; the importance of passing the fingers up to the forearm of the child is not mentioned. In manual removal of the placenta the author says:
"When you think you have separated the whole placenta, pull it away." This is not good advice. The operator should make sure the placenta is all detached, and then express the hand and placenta by pressure over the fundus of the uterus. The illustration shows the right way to express the hand and placenta.

The chapters on the care of the infant, both healthy and unhealthy, are excellent and full of sound advice. There is only one statement to take exception to, which is: "After the end of the first month let the baby be fed every three hours during the day." These intervals are too long.

These criticisms are not made with any idea of depreciating the value of this book. The work is carefully produced, and the teaching sound, whereas the errors referred to are very few and on minor points.

# MEDICAL NEWS IN BRIEF.

Sanitary Inspectors' Association.

THE 26th annual dinner of this Association was held at the Gaiety Restaurant on Saturday last, the President, Sir James Crichton-Browne, occupying the chair. Sir Alfred Keogh, Director-General of the Army Medical Department, appealed for 2,000 men for the sanitary service of the Territorial Army. Sir James Crichton-Browne said that in no branch of science had advance during the last 50 years been more decisive than in sanitation and the public health. But there was no finality in sanitation; on all hands problems-pressed for solution. Looking forward, one could see-that the advance of aeronautical inventions would involve an entirely new system of sanitary regulation. In regard to dust raised by motor-cars, the visible dust kept the nation sneezing, coughing, and sniffling; but after the visible dust subsided clouds of invisible dust hovered about. The improved sanitation of modern times gave confidence when danger threatened, pre-venting that panic in the presence of epidemics which had often resulted in mental overthrow. The President, on behalf of the Association, presented to Mr. G. Anderson, Chief Sanitary Inspector of Middlesbrough, an illuminated address, cases of cutlery, and a diamond ring, to mark appreciation of services rendered during 16 years as chairman of the north-eastern centre, member of the central executive, and chairman of the council during the years 1906-8.

#### Priendly Societies and Medical Men.

ORGANISED by the Charity Organisation Society, a conference was held on Saturday to discuss the question of friendly societies and the medical profession.

Dr. James Pearse, M.D., said the profession did not object to the principle that friendly societies should provide medical attendance for their members.

<sup>(</sup>a) "First Lines in Dispensing." By E. W. Lucas, F.I.C., F.C.S., Pharmaceutical Chemist, late Examiner to the Pharmaceutical Society of Great Britain. London: J. and A. Churchill. 1908.

(b) "Rotunda Midwifery for Nurses and Midwices." By E. T. When M. D., late Assistant Master, Ectunda Hospital. Pp. 294, 115 illustrations. London: Henry Frowde, Hodder and Stoughton. 1908.

objected to the details by which the principle was carried out. He gave as an instance that, taking the average of the friendly societies, the fee paid by members for medical attendance was 5s. per annum, and the practitioner had to supply free drugs and surgical dressings. He referred to the injustice of members in receipt of good incomes going upon the club. One such man was chief manufacturer in his district, and kept hunters, while another left estate valued at £80,000.

Sir Thomas Smith, F.R.C.S., deplored that there was no board of conciliation to settle the dispute between the societies and doctors. Sir Thomas Barlow, M.D., F.R.C.P., appealed to the sense of right and justice of skilled artisans to remember that very often the doctor did not get remunerated. Doctors deserved a living wage. Mr. R. W. Moffrey (Manchester Union of Oddfellows), on behalf of the societies, promised that, with a view to a settlement of the dispute, the National a view to a settlement of the dispute, the National Conference of Friendly Societies would receive a deputation of doctors. Dr. Smith Whitaker said no amicable adjustment could be arrived at unless friendly societies were prepared to accept a wage limit, by which all members receiving an income above a certain amount should not receive the attendance of the medical officer. medical officer.

#### British Medical Benevolent Fund.

A MEETING was held yesterday at the Royal College of Physicians on behalf of the British Medical Benevolent Fund, which was established for the relief of medical men, their widows, and children when in

The chair was taken by the President of the fund. An address was delivered by the Bishop of Oxford, supcollege of Physicians, and others. The fund was founded in 1836, so that for more than 72 years it has continued its beneficent work. It has slowly accumulated invested funds, out of the income of which it now supports 126 annuitants, spending in this department about £2,500 annually. No candidate under the age of 60 is eligible for an annuity. Many distressing cases, however, occur at a much earlier age, and for these relief has to be provided from the subscriptions and donations of the year, which are a fluctuating item of income. The grant department of the fund has caused much anxiety to the managers, for the capacity of the fund for good is limited by the contributions for the year. The main support of the fund comes from the medical profession itself, and little is given by the public at large. Yet, it is urged, there is no profession which does so much for the public with so little or no remuneration. The managers believe that the work and objects of the fund only require to be known and realised for the financial support which is necessary to be forthcoming.

The investments are placed in trust securities. The

accounts are audited every year by chartered accountants, and the working expenses are under 6 per cent. Contributions may be sent to the hon. treasurer, Dr. Samuel West, 15 Wimpole Street, London.

Marathon Racing.
"We have no hesitation in saying that we consider that school and cross-country races exceeding one mile in distance are wholly unsuitable for boys under the age of 19, as the continued strain involved is apt to cause permanent injury to the heart and other organs." This statement in condemnation of long-distance racing for boys, signed by Sir Lauder Brunton, Sir Thomas Barlow, Sir Alfred Fripp, Dr. James F. Goodhart, and Dr. W. Hale White, is being sent to every headmaster in the United Kingdom and the Colonies by Mr. J. Herbert Farmer, captain of the Old Harrovians and the Middlesex County Football Club from 1886 to 1891.

#### Prevalence of Mossles.

LONDON's annual death-rate the week before last, according to the Registrar-General's return, was 17.8 per 1,000, having been 18.0, 16.9, and 15.3 in the preceding three weeks. The total number of deaths registered was 1,653, and the births 2,110. There were 82 deaths from measles, compared with 76 in the previous week. In the 76 great towns of England and Wales the annual death-rate per 1,000 of their aggregate population was 18.0; in the preceding three weeks it had been 17.5, 16.6, and 15.7.

#### Reyal University of Ireland.

AT a meeting of the Senate, held on February 5th, 1909, the following examiners were appointed:—In Physiology: Thomas H. Milroy, M.D. Medicine: James A. Lindsay, M.A., M.D., and Joseph F. O'Carroll, M.D. Surgery: Thomas Sinclair, M.D., M.Ch. Ophthalmic Surgery: Arthur W. Sandford, M.D., M.Ch., and Louis Werner, M.B. Midwifery: Sir John W. Byers, M.A., M.D., M.A.O., and Alfred J. Smith, M.B., M.Ch., M.A.O. Medical Jurisprudence and Sanitary Science: Patrick T. O'Sullivan, M.D., and James N. Meenan, M.B., D.P.H. Materia Medica: Martin Dempsey, M.D., and Sir William. Whitla, M.A., M.D. Pathology: Edmond J. McWeeney, M.A., M.B., Arthur E. Moore, M.B., B.Ch., B.A.O., and W. St. Clair Symmers, M.B. Sanitary Science: Sir Charles A. Cameron, C.B., M.D. Mental Diseases: George Revington, M.D., and J. O'Connor Donelan. AT a meeting of the Senate, held on February 5th, J. O'Connor Donelan.

#### Conjoint Examinations in Ireland.

The following candidates have passed the Third Professional Examination held by the Royal College of Physicians and Surgeons:—G. F. Allison, A. D. Clanchy, M. M. E. Coghlan, O. G. Connell, C. A. Farrell, J. W. Flood, F. H. Gleeson, P. Harrington, J. P. Johnston, D. J. Lyne, J. Mitchell, F. J. McManus, J. H. O'Neill, R. P. Thomson, H. Q. O. Wheeler, J. McG. Williams.

The following candidates have passed the Supplementary of the collowing candidates the collowing candidates th

The following candidates have passed the Supplemental Preliminary Examination:—T. S. Ambrose, J. F. J. Carroll, M. Cahill, J. J. Cosgrove, J. P. Grimes, J. M. Marron, P. W. O'Connor.

# Indian Medical Service.

At the competitive examination for commissions in the Indian Medical Service, held on January 25th and five following days, 32 candidates presented themselves for 12 vacancies. The following is a list of those who were successful, arranged in the order of merit:—Henry Charles Semon, M.A., Oxford University and University College Hospital; Vinayak Balvant Gokhale, University College Hospital; Vinayak Balvant Gokhale, Bombay University and University College Hospital; Andrew Monro Jukes, St. Bartholomew's Hospital; Gwilym Gregory James, Westminster Hospital; William David Keyworth, B.A., Cambridge University and Charing Cross Hospital; Berkeley Gale, M.B., Glasgow University; John Howard Horne, M.B., Edinburgh University; Harold Holmes King, M.B., St. Bartholomew's Hospital; Mozaffer Din Ahmed Kureishi, King's College Hospital; Richard Edward Flowerdew, M.B., Aberdeen University and St. Thomas's Hospital; M.B., Aberdeen University and St. Thomas's Hospital; Alfred John Lee, M.B., University College Hospital; John Glendinning Bryden Shand, M.B., Edinburgh University and Extra-Mural School.

An inquest was held at Clerkenwell, on Feb. 2nd, on the body of an infant whose death was mainly due to inflammation set up in a way which for some time could not be accounted for. It was eventually ascertained that the mother had washed the child's clothing in a strong bleaching powder which contained alkali as one of its ingredients, and a doctor said that this caused an irritation which eventually resulted in very bad inflammation.

At the Warneford Hospital, Leamington on February 3rd, a portrait in oils of Dr T. W. Thursfield, senior honorary physician to the hospital, painted by Miss Edwards, was presented to the hospital, and was hung in the Board Room. Major Chesshyre Molyneux (chairman of the committee) presided and made the presentation. He said that in recognition of Dr. Thursfield's valuable services as their honorary physician, the portrait was presented by his colleagues of the staff and committee, and by other friends.

# **NOTICES TO** CORRESPONDENTS. &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a Distinctive Signature or Instial, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January let and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

#### ADVERTICEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.;
Quarter Page, £1 5s.; One-eighth, 12s. 6d.
The following reductions are made for a series:—Whole Page, 13
Insertions, at £3 10s.; £5 at £3 3s.; £2 insertions at £3, and
pro rata for smaller spaces.
Small announcements of Practices, Assistancies, Vacancies,
Books, &c.:—Seven lines or under (70 words), 4s. &d. per
insertion; 6d. per line beyond.

DR. SLINGSRI.—Has our correspondent tried the new test for suspected pancreatic disease? It is simple, and is said to be likely to prove perfectly trustworthy. A few drops of adrenaline solution are placed in the conjunctival sac of the patient: after a brief interval, should diabetes or pancreatic tumour be present, a marked mydriasis is observed. On the other hand, no dilatation of the pupil occurs when the pancreas is unaffected. OMEGA.—Whether aphasia is or is not associated with hemiplegia is merely a question of the extent of the primary lesion.

SIR CHARLES BALL ON THE RECTUM.

SIR CHARLES BALL ON THE RECTUM.

WE desire to correct two errors which were allowed to appear in our review of this very excellent work. Fig. 60 was by a slip described as a micro-photograph, whereas, as is mentioned beneath it, it is a drawing made by the aid of the camera lucida. We also were in error in thinking that Fig. 59 had been inadvertently turned upside down. That is not so. The photograph was originally taken from behind, with the patient in a stooping position. Contrasted with Fig. 59, it gave us the impression that it had been reversed. The position of the scrotum, however, obviously shows that this is not so.

LAY READER (London).—The nutrient qualities of "Mellin's Food" render it suitable for use, both by invalids and nursing mothers. A postcard directed to the firm, desiring further information, would, no doubt, secure for our correspondent a copy of the published reports upon this excellent preparation.

Mrs. S. L. P.—The active ingredient in the preparation is eucalyptus oil, which is a mild antiseptic, and a slight stimulant

# Mellin's Food

Mellin's Food is adapted for the use of children of all ages,

for the following reasons—

- Chemical and microscopic tests prove MELLIN'S FOOD to be absolutely FREE from starch.
- MELLIN'S may be used in varying quantities to adjust the proportion of Carbon and Nitrogen.
- 3. MELLIN'S aids the emulsification of fats.
- 4. Assists digestion without usurping the functions of the digestive secretions.
- Supplies valuable organic compounds of Phosphorus and Potassium.
- 6. May be used in any variable proportion which the demands of the child or the experience of the physician may dictate.

MELLIN S FOOD has received the highest awards at the International Exhibitions held during the past 40 years.

Samples of MELLIN'S FOOD, with tables of analyses, sent FREE to Members of the Medical Profession.

MELLIN'S FOOD, Ltd., Peckham, London, S.E.

# "FORMOLYPTOL"

is an elegant and refined combination of Formaldehyde (0.2%) Aceto-boro-glyceride (5%) together with the active antiseptic, balsamic constituents of Pinus Pumilio, Eucalyptus, Storax, Benzoin and Myrrh.

The mouth, "the vestibule of the body" is the microbic approach to the system, hence from every dental office should be preached the gospel of the "mouth bath."

Formolyptol does not stain or irritate, has no action upon gold crowns, is soothing, healing and possesses actual germicidal value. Indicated after extraction, in ulcerated conditions, Riggs Disease as a mouth wash, etc.

AN ADJUVANT TO, OR SUBSTITUTE FOR, THE MOTHER'S MILK.

# The Allenburys' Foods.

THE "ALLENBURYS" MILK FOOD, on the addition of water as directed, forms an accurately estimated humanised milk, and may be given to the infant at the same time as the mother's milk. It has been proved by clinical experiments to be as easy of digestion as human milk. No digestive disturbance is caused by giving alternate feeds from the

breast and the "Allenburys" Bottle. Weaning can therefore proceed gradually with comfort—both to mother and child. In addition to the above the "Allenburys" Milk Food No. 1 is free from all fermentive and pathogenic organisms. It is slightly alkaline as mother's milk, and has not suffered the acid decomposition which so usually affects cow's milk, and is the cause of much digestive and other trouble.

A Sample, with full particulars and analyses, will be sent on request.

# LISTERINE

# The standard American antiseptic for internal and external use

Awarded Gold Medal (Highest Award) Lewis & Clark Centennial Exposition, Portland, 1905; Awarded Gold Medal (Highest Award) Louisiana Purchase Exposition, St. Louis, 1904; Awarded Bronze Medal (Highest Award), Exposition Universelle de 1900, Paris.

The word Listerine assures to the Medical Profession a non-poisonous antiseptic of well proven efficacy; uniform and definite in preparation, and having a wide field of usefulness.

Listerine represents the maximum of antiseptic strength in the relation that it is the least harmful to the human organism in the quantity required to produce the desired result; as such, it is generally accepted as the standard antiseptic preparation for general use, especially for those purposes where a poisonous or corrosive disinfectant can not be used with safety. It has won the confidence of medical men by reason of the standard of excellence (both as regards antiseptic strength and pharmaceutical elegance), which has been so strictly observed in its manufacture during the many years it has been at their command.

The success of Listerine is based upon merit, i.e., the best advertisement of Listerine is Listerine.

# LAMBERT PHARMACAL COMPANY,

ST. LOUIS, U.S.A.

In combating serious illness, it is doubly important to be assured that the patient is supplied with genuine Listerine, as the substitutes sometimes offered by the trade are generally of undetermined antiseptic strength, and too often worthless for the purposes for which they are required.

# Notes and Comments.

An Appendicitis Dinner.

America is the chosen abode of freakishness, and in one of its most recently reported essays it has certainly lived up to its reputation. From a New York journal we learn

that a Philadelphia surgeon gave a dinner to patients upon whom he had operated for appen-The story tells that no fewer than 160 guests graced this eccentric banquet, a living and eloquent testimony of the skill of their dis-tinguished host. It is to be presumed that he alone would be conscious of the unseen failures who might possibly be hovering in the spiritual atmosphere of the banqueting-room. In any case, the number of operations mentioned can hardly be regarded as excessive for any surgeon who has been for any considerable length of time engaged in operating practice. The first operation for appendicitis appears to have been performed in New York in 1886, although it had been originated and practised in England some years previously by Sir Frederick Treves. In Philadelphia the first formal removal of the appendix appears to have taken place in 1887, and to have been then performed as a precautionary measure. Later the operation was undertaken in a wholesale fashion, and even now, although the craze has lapsed into saner moods, it seems not unlikely that the physician might be able to cure not a few cases that are handed over to the tender mercies of the surgeon.

Further

In spite of a chequered career, it is clear that the operation for appen-Side-lights on dicitis has saved tens of thousands the Appendix. of lives, and that it stands out prominently as one of the great ad-

vances of the marvellous century which produced Listerism. It is a matter, perhaps, for some little amount of self-congratulation that both discoveries should have emanated from the practical genius of our own countrymen. Curiously enough, the ætiology of appendicitis yet requires a good deal of illumination. In a general sense it seems more than probable that bacterial invasion lies at the root of the inflammatory process in a majority of That statement, however, does not help us much in the direction of prevention or of treatment -whatever its outcome may be in the more or less remote future. It is all very well to scoff at the public for their fixed belief in the agency of grapestones and other foreign bodies in the causation of the malady, but medical teaching, on the other hand, is still vague and unsatisfactory. As a matter of fact, out of 1,000 cases of appendicitis operated upon at the Johns Hopkins Hospital, foreign bodies were present in only four of the

whole number. The recent operation of appendicostomy although undertaken for causes other than inflammation of the appendix, has, we understand, already been somewhat extensively practised. Useful as it undoubtedly appears to be in suitable cases, we sincerely hope that it may never be permitted to lapse into that indiscriminate application which has cast somewhat of a slur upon operative surgery in the case of the removal of the appendix.

without Protection.

Pre-eminent tinually being told by one type of politician that British trade is on the down grade, and that the enterpris-

ing foreigner is ousting the nation of professed shopkeepers from their heritage, it is reassuring to learn that in the trade of surgical instruments the Britisher can hold his own in foreign markets, in spite of all disadvantages and restrictions. If this is the case, as we gather it to be from what has lately been written on the subject, it is certainly comprehensible, for most Britishmade surgical instruments, albeit very expensive, are of the finest quality and workmanship, and will hear comparison with those turned out by any nation. It seems that English scalpels and knives generally are especially esteemed, and that the demand for them among American surgeons is extensive. This is high commendation, coming as it does from a land which flows with iron and steel, and in which blast-furnaces on a prodigious scale have to work day and night to keep up with orders for rails, plates, and the coarser steel goods. The craft of surgical instrument-making, indeed, in this country has certainly reached a high pitch of perfection, and we understand that it is one of the few callings which is not over-stocked, as the difficulty of getting first-rate workmen is so great that an accomplished hand will never want for plenty of highly remunerative employment. When so many of the trades in which this country held pre-eminence for so long are being cut into, it is comforting to think that in this special line Great Britain more than holds her own.

Expensive

THE ways that they have in New York City, when compared with the

Expensive
Expectoration. conservative doings on "this side," possess a naïveté which is almost comic. It appears that the City Health Commissioner for that great centre has a "sanitary squad," one of whose latest duties is to institute prosecutions for spitting in public places. The squad took the aggressive last week, and netted no less than 200 persons who thus offended against hygiene and good taste. The culprits all committed their offences in railway trains and tubes, and we can candidly say that any sanitary squad which a medical officer of health over here turned on to the same job would receive our hearty support. It seems that the regulation against spitting has not been realised by the American public yet, and that it is something of a wrench for them to abandon so old-established and popular a national habit. When haled before the magistrate the only defence recognised was that the spitting was not done for pleasure, but for business, that is to say, that the prisoners were suffering from a cough. Even this was only admitted as an extenuating circumstance, and the valiant 200 were all fined a dollar, except those with coughs, who got off with half that sum. The campaign, which has been instigated by the American Anti-Consumptive Association, bids fair to be carried on with vigour and success, and soon catching spitters will probably become as remunerative a form of sport in New York as motor-trapping is to the police in Surrey.

Oxygen and Sport.

DR. LEONARD HILL is certainly interesting the world by his advocacy of oxygen, and his lecture at the London Institution last week has attracted much notice. Dr. Hill

finds that oxygen has a wonderful effect on athletes, especially those who are not in training. He got two men to box the other day, one a novice and the other an old hand. At the end of two rounds the novice was winded, so that his opponent could, if he desired, walk round him; a draught of oxygen was then administered, and forthwith the staying powers of the tyro were wonderfully increased. "There is no doubt," said the lecturer, "that the taking of oxygen before an athletic event would result in the breaking of records. We have tried it in hockey and football teams, and in every case oxygen has had a good effect." This may be good physiology, but it is bad sport. The object of a game is to test the natural prowess and staying power of the individual man, not to test the value of artificial aids to those of inferior physique. And we are not sure that it is even good physiology, for who is to say that the habit of taking oxygen for athletic contests might not lead to irritation of the bronchi, and even dilatation of the heart from the increase of unnatural strain? The use of oxygen for emergencies, such as to aid those descending into mines when explosions have occurred, or for firemen entering burning houses, is legitimate and praiseworthy, but let us have our athletic contests, at least, oxygen-barred.

Compensatory
"Phlebitis."

Surely the nadir of absurdity in workmen's compensation claims was plumbed at Cardiff the other day, when a carpenter sued his employers in the County Court for illness re-

sulting from a flea-bite. The case was brought in all seriousness, and a dramatic touch was lent by the solicitor for the plaintiff asking for an adjournment on account of his client's state of health preventing him from appearing in Court. This plea, it is true, was somewhat discounted by the fact that a man told his Honour directly the adjournment was granted that he had seen the claimant in Court that morning, and when the case came on again later neither solicitor nor client put in an appearance. Nevertheless, the case was opened and pursued up to a certain point with the usual forensic vigour, but even the gravity of the judge was not proof against the tomfoolery of the proceedings. His Honour naturally wanted to know how it was to be proved that the flea did not perpetrate the

assault in the stilly watches of the night, and, equally naturally, no proof was forthcoming. After the collapse of this case landladies who let seaside lodgings may breathe again, for if it had been held that a flea-bite was a tort, surely the gains of the occupation of many of them would rapidly disappear. There is, nevertheless, a serious side to a claim of this type. It is grossly unfair that an employer should have to bear the expense of defending himself in such an action—expense which, of course, he will never be able to recover from the claimant.

# LEADING ARTICLES.

THE EARLY TREATMENT OF INSANITY.

ONE of the less satisfactory features of the scientific treatment of mental diseases is the comparatively small proportion of cures effected under the best modern conditions. In dealing with this class of maladies, experience impresses upon our minds forcibly the unerring wisdom of the old saw which tells us that "prevention is better than cure." Indirectly, a vast amount of insanity could undoubtedly be prevented by the lessening of such common and potent causes as alcohol and syphilis. In that direction the general physician is capable of diverting from the asylums a fairly full stream of potential insanity. His achievements of that kind, however, from the nature of the case, cannot be tabulated and put on record. It is only when we turn to incipient mental disease that we are able to gauge with any approach to accuracy the effects of systematic diagnosis and treatment. In this respect, the foundation of a Mental Hospital in London marks a most important departure in a difficult and, in many ways, obscure branch of medical research. The undertaking is fully noted in the Nineteenth Annual Report of the Asylums Committee of the London County Council. It will be remembered that in February, 1908, Dr. Henry Maudsley offered the County Council a contribution of £30,000 towards the cost of the erection and equipment in London of a hospital of 100 beds for the treatment of cases of recent and acute mental disorder. This generous offer was accepted by the Council, which has caused plans to be prepared, and is now looking out for a suitable site for such a hospital. The prospect of such an addition to the machinery, so to speak, of scientific medicine will be hailed with satisfaction by all who are interested in that most important branch of intellectual activity. pointed out by the chairman of the Asylums Committee, the most forcible argument for the provision of the proposed institution, from the patient's point of view, is the fact that it will provide opportunity for individual treatment and close personal attention, which are all important in the early stages of mental disturbances. At the present time there is little opportunity for the effectual classification of patients in the wards of the asylums, where the population consists to a preponderating extent of patients whose mental condition is ohronic, and who are therefore dealt with collectively. Patients of that class call for detention rather than for treatment, as their cases are for the most part hopeless as regards cure. In Dr. Maudsley's hospital, on the other hand, only those patients will be detained for whom treatment is necessary and who respond to it. Chronic cases will not be received, or only for a brief period of detention, in order to ascertain the fitness or otherwise of the individual patient for ordinary asylum treatment. The pith of the matter is well put in the following passage from the above-mentioned Report:—There will be in the hospital an entirely different atmosphere from that of the ordinary asylum, an atmosphere, as Dr. Maudsley expressed it, of sanity as opposed to one of insanity. The hospital will be essentially an institution for providing treatment, the direct object of which will be the cure and discharge of the patient." Other valuable possibilities are opened up by the foundation of an institution of this kind in the heart of London. There will be, for instance the possible association with the scheme of various physicians and surgeons distinguished in the particular branch of medical science immediately concerned. Then there will be the inevitable corollary of an out-patients' department, an organisation, the need of which has been recognised for many years past. Another point is the probable creation of a great central teaching organisation for those desirous of acquiring a knowledge of mental diseases. As the Council pertinently remark: - "In Berlin, Munich and other cities and towns in Germany, a psychiatrical clinic and laboratories are associated with the university, and the effect has been the rapid development of clinical and pathological knowledge of mental diseases, and the proper systematic training of asylum officers, graduates and post-graduates in psychological medicine." The thanks of the public, no less than of the medical profession, are due to the London County Council for the prompt and liberal spirit in which they have accepted Dr. Maudsley's offer. From time to time we have felt it our duty to criticise that body, but on the present occasion we have nothing but praise for the way in which they are adopting a scheme that promises to confer great and lasting benefit upon the community.

# CURRENT TOPICS.

# Surgical Convalescence.

A SOMEWHAT novel appeal is being made by H.R.H. Princess Louise and some other philanthropists on behalf of a charity. They have been instrumental, with others, in starting a small home at Eastleigh for surgical convalescents, where patients with wounds requiring dressing and care are received. In most convalescent homes such cases are not received, and none need more the benefits of country air and surroundings. The proposal has now been made to extend the sphere of usefulness of this work by establishing within twenty or thirty miles of London a permanent home whither patients could be taken by motor ambulance. An opportunity has recently offered for securing a house and grounds admirably suited for the purpose, and within easy reach of London. But the committee are bound by their trust deed not to purchase until they have a funded income which will enable them to meet the necessary ex-

penses. A considerable amount has already been obtained, but it is calculated that a total sum of £30,000, producing from £900 to £1,200 per annum, will be required to put the attempt on a safe footing for providing 21 beds, which will accommodate an average of 200 patients yearly. We do not know quite how so large a number is to be accommodated at so small a price, but that is a matter for the committee; what we do recognise, however, is that this is a genuine reform in the usual way of providing for the wants of the sick. The usual method is to plunge into debt and then appeal to the public to wipe it off, and this unbusinesslike procedure has done much to discredit hospital finance and hospital methods. The present scheme is as creditable to the head as it is to the heart, and it has the backing of the King himself and seven of the leading London hospitals. We wish it the success it so well merits.

# Advertising Methods.

EVERY medical man is pestered every day by circulars of all sorts and conditions advertising goods which vary in kind from good drugs to bad cigarettes, and only a waste-paper basket as capacious as that of the editor's of a halfpenny morning journal stands between him and-let us say-golf-language. We have little objection to the straightforward firms who put their names on the outside of the envelopes, or the moneylenders who mark their communications "private," because each saves the recipient the trouble of undoing the envelope. Within a few years of appearance on the Medical Register, the doctor developes a new reflex in the deltoid, which acts immediately the envelope is brought within the visual field, and casts the irritating missive into the waste-paper basket before the brain has received the message from the eve. It becomes the business, therefore, of traders who would overcome this automatonism to devise methods for deceiving the old medical hand, and a certain firm of wine merchants, to which we will not give the benefit of a gratis advertisment, have lately achieved a certain success in this line. The plan adopted is to send a bogus letter, signed merely by a Christian name, bearing the outward verisimilitude of a genuine communication which has gone astray. Relying on the scientific curiosity of the reader, they feel sure that a letter thus worded will be sure of perusal, and we gather that their confidence is, in the majority of instances, justified. These pushful people mark their list in two prices, one for the public and one for the medical profession, no doubt trusting that the apparent bargains will be jumped at by the unwary. We have no knowledge of the stuff advertised, but if medical men have no better reason for prescribing wine than that it is represented to them that they will receive preferential rates in buying it for their own table, we have little doubt that they will prefer to recommend a sound local firm which does not resort to these artifices.

# "Reform" at Bermondsey.

The recent issue of the Local Government Board Order with regard to unsound food and foreign meat has imposed fresh and responsible duties on

such local authorities as are connected with the importation and distribution of these articles of dietary. Among others is the Borough Council of Bermondsey, through whose district passes from 25 to 30 per cent, of the imported food of London. A proposal was recently made that three additional sanitary inspectors should be appointed to carry out the new duties, and vigorous opposition was offered by the "Reformers," whose idea of reform seems to originate and end in saving of the rates. One councillor declared that soon the borough would have as many sanitary officials as inhabitants, and he suggested that if they had a little less sanitary science and a little more common sense in the administration of local affairs, it would be very much better for the health and good of the people and the convenience of the inhabitants. Fortunately the proposal was carried, in spite of the lamentations of gentlemen of this cirrhotic kidney, but outbursts of this kind tend to show how difficult is the work of real reform. The almost complete absence of food inspection has long been a crying scandal, and England, which is supposed to lead the way in most sanitary matters, is far behind most countries in this question. The addition of three modestly-salaried inspectors to deal with the food passed through a borough with the enormous river frontage of Bermondsey is surely the minimum of what might be expected in the way of discharging the responsibilities incurred in its trade in the food of the masses.

The Pathology of the Common Cold. The pathology of the "common cold" ought to be one of the most obvious of our pathological teachings, if abundance of opportunity of studying it was sufficient. Nothing is so irritating to the ordinary man as to be laid up temporarily by so trifling a cause, and one for which apparently so little can be done. An interesting contribution to the pathology of nasal catarrh appeared towards the end of last year in a contemporary. The writer, Dr. D. W. Allen, considers he has placed the bacteriology of colds on a sounder footing, and has shown how the causal organism may be recognised from the symptoms. He also thinks he has demonstrated the value of vaccine therapeutics, not only in shortening attacks, but in permanently curing chronic cases. There are five classes of organisms, one or more of which are to be found in the throat in cases of common cold. Dr. Allen states that the micrococcus catarrhalis and the bacillus septus affect the fauces and pharnyx first, and that the former also affects the trachea in company with the micrococcus paratetragenus. The symptoms are only severe in cases in which the bacillus influenzæ septus affects the fauces and pharnyx first, and that the former also affects the trachea in company with the micrococcus paratetragenus. The symptoms are only severe in cases in which the bacillus influenzæ is present. Chronic nasal catarrh is nearly always found to be due to infection with the bacillus of Friedländer. Dr. Allen records one most successful case of vaccine therapy. A friend of his who always suffered from colds after a railway journey was given an injection of 275,000,000 dead organisms shortly before starting on one. Despite

a very long and cold night journey, for the first time for years he developed neither sore throat nor nasal catarrh, nor during the succeeding twelve months has he developed a cold at all. If every one who suffers from cold could get such easy and permanent relief, we should hear less of anti-vivisectionist objections to serum and vaccine remedies.

#### Sweating by the Post-Office.

It has come to our knowledge recently that the Post Office is still endeavouring to obtain medical attendance for its employees at scandalously inadequate rates of remuneration. The rate usually offered is one of 8s. 6d. a head per annum for all employees in the district who have wages amounting to less than £150 a year. In addition to medical attendance on the Post Office servant and supplying him with medicines, the surgeon is expected to furnish half-yearly reports on the sanitary condition of the various post-offices in his district, and perform several other onerous duties, without any additional fee. For attendance on "itinerant" servants a fee of 2s. 6d. per consultation is granted, to cover advice and medicine, but no sum greater than 8s. 6d. is to be paid for attendance on any one patient in one year. In a populous city it is possible that these fees might remunerate a man to some extent for his work, but in a scattered country district, where perhaps only three or four persons are employed, the services required would not be adequately paid for at five times that sum. In addition, it is to be remembered that many of the employees, earning from two to three pounds a week, are quite well able to pay for medical attendance. We trust medical men, to whom these posts are offered, will refuse them. Unanimity on the part of the profession is all-powerful in obtaining just reward for honest services, but so long as men are willing to accept starvation wages, so long starvation wages will be offered.

# Gratuitous Health Lectures.

WE publish in another column certain resolutions passed by the County Fermanagh Branch of the Irish Medical Association, protesting against the performance of so much gratuitous work by medical men in the health campaign at present being conducted in Ireland. It is quite truly pointed out that it is the duty of the State to provide instruction for the public in matters relating to public health, and that as long as the State is relieved of this burden by voluntary effort, it is not likely practically to recognise its responsibilities. The Women's Health Association of Ireland is doing excellent work throughout the country, but the greater part of this work is performed gratuitously by medical men. We are loth to say that medical men should stand out from such work, or refuse their aid, but it is unreasonable to expect that professional work, requiring large scientific knowledge, is to continue indefinitely to be given for nothing. These philanthropic societies must carry their independence a little further, and not remain satisfied to depend on the good-will and free labour of one class of the community. If medical men were properly remunerated for the lectures given under such organisations, then all

temptation to exploit their own work or skill would be removed; and we have had regretfully to remark on one or two occasions that lecturers had succumbed to this temptation.

# The Appointment of Lady Medical Residents.

Social Manchester has recently been rent into factions by the burning question of the appointment of lady house surgeons. This, that and the other reason have been given both for and against, but in matters of this complexion it is often hard to surmise the real inwardness of things. The lady medical has clearly come to stay, but so far she has certainly not proved an unqualified success as a hospital resident officer. The fact appears to be that she shares with the rest of her sex the inherited incapacity for responsible administration, which sits easily enough on the shoulders of any man who is worth his salt. Be the explanation what it may, the average lady resident drifts into hostilities with the administrative staff as readily as a duckling takes to the water. The experience is unfortunate, and is likely to be extremely harmful to the future education of the lady doctor. If she be wise in time, she will take steps to warn all aspirants to resident hospital posts of the difficulies inseparable from the position, but all of them, we are happy to believe, to be overcome by the exercise of common tact, prudence, and forbearance.

# PERSONAL.

THE KING has sent a letter to Mrs. Cox, wife of Mr. Harry W. Cox, the X-ray scientist, who recently had practically the whole of his right hand amputated as a result of X-ray dermatitis, asking that his deep sympathy may be conveyed to her "poor husband," of whose affliction His Majesty has heard with great sorrow. Mr. Cox is progressing as well as can be expected, though he is still very weak.

THE PRINCE AND PRINCESS OF WALES paid a surprise visit to St. Mary's Hospital, Paddington, on February 8th. The Prince and Princess inspected nearly all the wards in the old hospital, and conversed with almost every patient. They also visited the new operating theatre and the empty wards of the Clarence wing, which their Royal Highnesses greatly regretted to see were still unoccupied.

THE PRINCESS OF WALES will, on February 22nd, open the new ward for children at the Great Northern Central Hospital, Holloway, and receive purses containing subscriptions towards the cost of construction and equipment.

Dr. H. Herd, of Pendleton, has been appointed a Medical Officer in connection with the inspection of Manchester school children.

Dr. J. A. Haran, Medical Officer of the East Africa Protectorate, has been appointed Medical Officer of Health for Mombasa.

MR. SINCLAIR WHITE, F.R.C.S., Surgeon to the Royal Infirmary, Sheffield, has been elected a corresponding member of the Surgical Society of Paris.

THE LORD PRESIDENT OF THE COUNCIL has appointed the Hon. Mrs. Charles Egerton to be a member of the Central Midwives Board in the place of Miss Jane Wilson, recently resigned.

THE many English friends of Dr. Schuman Leclercq (Carlsbad, Austria) will hear with pleasure that he has been made Chevalier of the French Légion d'Honneur.

On February 18th, Dr. E. Graham Little will read a paper on "The Treatment of Skin Diseases by Ionisation," and Dr. F. S. Langmead one on "Infant Feeding with Undiluted Citrated Milk," at the Harveian Society.

DR. PROUT, C.M.G., and Professor Newstead, both of the Liverpool School of Tropical Medicine, arrived at Bristol on February 10th, on the completion of a tour of investigation in Jamaica.

HIS EXCELLENCY THE LORD LIEUTENANT OF IRELAND, the Earl of Aberdeen, has accepted the invitation of the President and Fellows of the Royal College of Surgeons in Ireland to the annual college dinner on Saturday, February 20th.

THE Annual Oration before the Hunterian Society was delivered by Dr. W. Rawes on February 10th at the London Institution, Finsbury Circus. The title of his address was "Psychiatry: A Retrospect."

LIEUT.-COLONEL J. W. T. GILBERT, V.D., Royal Army Medical Corps (Territorial), has received His Majesty's permission to accept and wear the silver medal of the Order of Orange-Nassau, conferred upon him by the Queen of the Netherlands.

PRINCIPAL SIR DONALD MACALISTER, K.C.B., M.D., Glasgow University, was the guest of the Edinburgh Royal Medical Society at the President's dinner in the Society's Hall, Melbourne Place, Edinburgh, on February 9th. The Senior President, Dr. W. Kelman McDonald, presided.

At the Royal Sanitary Institute, on Wednesday, March 3rd, a discussion will take place on "The Control of Infectious Diseases in Schools." It will be opened by D. A. Carruthers, M.D., D.P.H., County Education Medical Officer, Bucks.

DR. CHARLES EDWARD BEEVOR, F.R.C.P., of Harley Street, W., President of the Neurological Society, who died on December 5th, aged 54, left estate of the gross value of £41,439 16s. 2d., of which the net personalty has been sworn at £41,037 10s. 1d.

Dr. WILLIAM ALFRED ELLISTON, of Scothorne House, Felixstowe, Suffolk, a past President of the British Medical Association and of the Medical Defence Union of Great Britain, who died on November 27th, aged 68, left estate valued at £21,407 gross, with net personalty £11,349.

WE regret to learn that Dr. Vacher, medical officer for Cheshire, has tendered his resignation to the County Council. Dr. Vacher was the first medical officer appointed by the County Council. In accepting his resignation the Public Health Committee of the Council have placed on record their appreciation of the valuable services he has rendered to the county. A special committee has been appointed to arrange the duties and fix the salary, not exceeding £750 per annum, of the next medical officer.

# A CLINICAL LECTURE

ON

# MENINGEAL HÆMORRHAGE..

By PROF. H. CHAUFFARD, M.D.,

Physician to the Paris Hospitals.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

MENINGEAL hæmorrhage is much more frequent than is generally supposed. Froin, in his thesis (1903), collected twenty-seven cases of the kind admitted during a single year in two medical wards at the Cochin Hospital. Recourse to lumbar puncture, with the escape of a reddish fluid, has enabled us to establish the frequency of a lesion which most authors of text-books dismiss with a few general remarks.

The lesion is not only very common, but it often occurs in comparatively young persons. It does not, like cerebral hæmorrhage, wait for advanced age to declare itself, since it is met with at eighteen

or twenty years of age.

We may distinguish two varieties of meningeal hæmorrhage: (1) Cerebro-meningeal hæmorrhage, in which the extravasation of blood, commencing in the brain substance, subsequently spreads by diffusion into the meninges and the sub-arachnoid space; (2) meningo-cerebral or pure meningeal hæmor-rhage, in which the blood comes from a damaged meningeal arteriole, giving rise to slight pressure on the subjacent cerebral matter. Among his twenty-seven cases, Froin records thirteen instances of cerebro-meningeal and fourteen of pure meningeal hæmorrhage. As a matter of fact, cases of cerebral hæmorrhage are in most instances meningeal as well. The blood in cerebral hæmorrhage passes into the sub-arachnoid space, as shown by the pinkiness of the fluid withdrawn by lumbar puncture; indeed, we are thus enabled to distinguish between cerebral hæmorrhage and softening of the brain. In the latter the cerebro-spinal fluid remains clear and colourless. From the point of view of prognosis, cerebro-meningeal hæmor-rhage is necessarily of graver import than pure meningeal hæmorrhage, since it is indicative of a copious escape of blood, and is accompanied by extensive symptoms of paralysis, when, indeed, it does not entail immediate death.

Pure meningeal hæmorrhage not infrequently gives rise to temporary paralyses, and the prog-

nosis is not necessarily very serious.

This man, æt. 36, suffering from a lesion of this kind, has just recovered his health, or, rather, we may say, there only remains some mental disturbance with a tendency to fixity of ideas, all the other symptoms having cleared up. In 1903 he had sunstroke, after which his temper underwent a change. In 1904 he had an attack of acute articular rheumatism which left some damage of the encephalic vessels. Then, too, he was ethylic, drinking on an average six pints of wine a day. All these circumstances predisposed him to meningeal hæmorrhage. No syphilis.

On February 6th, after a little shivering and headache, he suddenly lost consciousness. He came to, was very excited and became delirious, then passed into a state of extreme prostration. He lay curled up in bed and for some hours there was conjugate deviation of the head and eyes, in addition to which he had symptoms of slight left facial hemiparesis and stiffness of the neck. Kernig's sign was well marked, the patellar reflexes were exaggerated, and he had ankle clonus on the

left side. Babinski's sign was not well marked, and its existence could not be affirmed. There was lateral nystagmus with inequality of the pupils, loss of reflex of contraction to light, slowing of the pulse, which went down to forty a minute. Percussion of the cranium was painful over the right parieto-temporal region, and it is worthy of note that this spot is often tender in cases of meningeal hæmorrhage.

It turned out to be a case of this kind. Lumbar puncture gave issue to fluid, under pressure, of a dirty pink colour, containing 92,000 red and 4,000 white corpuscles per cubic millimetre. There were, in addition, numerous giant cells and red cells (hæmato-macrophage cells). Examination of the fundus showed peri-papillary ædema with swelling of the veins and arterial ischæmia. All these signs cleared up in the course of a few days except the headache and neck stiffness, which lasted for some time longer.

Some days later, however, the headache and vomiting of green matter returned and the torpor became marked. The patient evidently had a recurrence of the bleeding, and on lumbar puncture the number of red corpuscles had increased. This was only a matter of a few hours, after which he again began to get better. All that remains is a tendency to obsessional ideas, as evidenced by his incressent demand for his wife and children.

incessant demand for his wife and children.

There are two other clinical signs to be noted: slowness of the pulse and, now and then, a slight rise of temperature. His pulse had fallen to 50 per minute, this being no doubt due to irritation of the medullary pneumogastric centre. In view of the fact that the injection of atropine determines tachycardia by stimulation of the paralysis of the vagus, we tried the effect of injecting a 200th of a grain of this alkaloid, but it had no effect. A second injection, this time of 100th of a grain, caused the pulse-rate to rise from 50 to 78, and this acceleration lasted until the following day. The second interesting clinical sign is the rise of temperature which is occasionally met with in these patients. The temperature goes up to 990 or 99.50 F., but this should not lead us to suspect a superadded infection. In cases of copious hæmorrhage the destruction of red corpuscles is the cause of the rise of temperature, which is practically an aseptic fever. In this case no such thermometric tendency was observed, the hæmorrhage no doubt being too small.

All the symptoms had cleared up in about a fortnight, but, as I have already noted, there only remains some intellectual torpor. He understands what is said to him, and reads and writes, but only when enjoined thereto by us, for he would not do anything of the kind of his own initiative. The treatment consisted in the application of ice to the head and lumbar puncture repeated every other day, each time withdrawing some 10 or 15 cubic centimetres of fluid.

The diagnosis of meningeal hæmorrhage is based on several categories of symptoms. In the first place, lumbar puncture gives issue to a pink fluid which establishes the nature of the affection at once,

and for a certainty. Then there are the meningeal symptoms: pain, headache, stiffness of the neck, Kernig's sign, slowness of the pulse, hemiparesis and vomiting. All these signs are common to tuberculous meningitis and cerebro-spinal meningitis, but the onset is quite different. In meningeal hæmorrhage there is an initial ictus, and, apart from exceptional cases of epidemic apoplectiform meningitis, this ictus is wanting. Moreover, symptoms of infection are usual in cerebro-spinal meningitis: herpes, septicæmic eruptions, nephritis, arthritis and endo and pericarditis. None of these symptoms are met with in association with meningeal hæmorrhage, which is an aseptic process.

Some of the symptoms are compatible with an erroneous interpretation, such as the headache, which may simulate uræmic headache. Then, too, meningeal hæmorrhage is very apt to attack elderly persons, the victims of arterio-sclerosis, or who are suffering from interstitial nephritis, and, as they may also be albuminuric, we may remain in doubt for the time being. I can recall the case of a private patient who had had an ictus followed by intense headache. There was a history of syphilis, and his urine contained albumin. It might have been cerebral syphilis or uræmia. The question The question arose whether to prescribe an anti-syphilitic treatment. Lumbar puncture gave exit to a pink fluid, so that it was a case of meningeal hæmorrhage, and the treatment had to be directed to the nephrosclerous condition, and not to the syphilis.

The presence of glycosuria sometimes renders the

diagnosis difficult. I remember the case of a patient who was admitted to hospital in a state of coma. His urine contained sugar, but there was no acetonic odour of the breath, nor was the breathing sighing. The temperature, moreover, was slightly raised. Lumbar puncture showed that the glycosuria was secondary to meningeal hæmor-rhage, and, as a matter of fact, the sugar had disappeared from the urine within a few hours.

In other cases we get some paresis with facial paralysis, visual disturbances, and limited pain on percussion over the cranium, which may throw

light on the nature of the lesion.

The prognosis, as I have pointed out, is vastly graver in cerebral-meningeal hæmorrhage. Meningeal hæmorrhage is much more likely to be recovered from (three deaths in thirteen cases). In fatal cases it is often very difficult to discover whence the blood has come, so copious is the bleeding.

The distant future of these patients is, on the whole, favourable. A woman who was attacked in June, 1903, by meningeal hæmorrhage, with extremely intense headache, general contractures and left hemiparesis, was all right again in a month, with the exception of moderate exaggeration of the patellar reflexes. She came back to the hospital in February, 1908, complaining of headache, with weakness of the right arm. She dreaded a return of her previous troubles, but in reality the symptoms were due to hysteria. Lumbar puncture revealed nothing abnormal, and the symptoms cleared up in the course of the next few days.

In another case the patient was seized with mental disturbances, showing that we must make certain reservations. She was 65 years of age, and on February 21st, 1907, she suddenly became comatose On lumbar puncture the fluid was coloured; there was some fever during the next few days (99.5° F.), with slight contracture of the In the course of a fortnight she was lower limbs. doing well, but then the mental disturbances supervened: delirium, visual hallucinations and restlessness. She got up and ran about the ward, depositing her motions on the floor, sheets, &c. The lumbar fluid was clear. She was sent to an asylum

for the insane where general enfeebleness of the intellectual faculties was noted.

The present patient, as I have mentioned, also remains in a state of mental conubilation, and the tension of the cerebro-spinal fluid is still high. Possibly the intellectual torpor, to which attention has been called, is due to cerebral compression, secondary to this exaggerated intra-cerebral pres-

In the matter of treatment we must studiously avoid giving hot baths, a reason for distinguishing clearly between this lesion and cerebro-spinal meningitis, in which hot baths constitute an important factor in the treatment.

We practice lumbar puncture every two or three days, withdrawing from 10 to 15 cubic centimetres of fluid. The patient is kept in a state of absolute cerebral repose, with ice to the head, dry cupping down the vertebral column, and is put on milk diet. This sums up the treatment, but if the headache becomes intolerable, certain analgesics, such as phenacetine, will be useful in affording a measure of relief.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Prof. James Alexander Lindsay, M.D., F.R.C.P.Lond, Professor of Medicine, Queen's College, Bel-fast. Subject: "Uncommon Types of Common Diseases."

# ORIGINAL PAPERS.

SOME PRACTICAL POINTS IN THE TREATMENT OF INDIGESTION IN INFANTS. (a)

By ERIC PRITCHARD, M.A., M.D.Oxon, M.R.C.P.Lond.,

Assistant Physician to the Queen's Hospital for Children, &c.

Dr. Pritchard explained that the milk of all species of mammals was designed to develop the form of stomach that was required by the offspring. Thus mare's milk was a thin, digestible fluid which coagulated in a gelatinous clot which could pass rapidly and immediately through the pyloric opening without further digestion. These characters in the milk favoured the development in the foal of a small, functionally inactive stomach, and threw the strain of digestion on the intestines. In the adult horse the volume of the stomach represented only 8 to 9 per cent. of the whole alimentary canal; in fact, the stomach could only contain about onethird of a full meal, hence the necessity for the rapid transit of food through this organ.

In the cow the stomach was enormous, and, from a functional point of view, most active. volume it represented about 60 per cent. of the whole alimentary canal. Hence it was important that in the calf the incidence of digestion should fall on the stomach. Cow's milk was admirably designed to achieve this object; it coagulated in the stomach in a heavy, bulky olot, and required considerable digestion before it could pass through

the narrow pyloric opening.

In many respects human digestion stood midway between that of the horse and that of the cow; the volume of the stomach was about 20 per cent. of the entire digestive tract. The pylorus was not so open as in the horse, nor so well guarded as in the cow. Food remained, or should remain, in the stomach a short time as compared to the period required by the cow, and a long time as compared to that required by the horse. Human milk, owing

<sup>(</sup>a) Paper read before the Chelsea Clinical Society, January 19th, 1909.

to its physical and chemical characteristics, developed digestive powers of the kind required. It was, however, interesting to note that the training or development of the stomach was very beautifully graduated by means of colostrum. Colostrum did not coagulate in the stomach, neither did it contain milk sugar which could undergo lactic acid fermentation. Thus in the new-born infant there were no elements in its natural food to lead to dilatation or premature development of the gastric

The transition from incoagulable albumens to coagulable caseinogen was slow and gradual, and the same was true of the transition from dextrose to milk sugar or lactose. An appreciation of these provisions of Nature would explain why gastric digestion was so frequently disturbed in infants by the administration of unmodified cow's milk, which was designed to develop a large and dilated stomach.

In those cases in which artificial feeding was adopted from the first it was of the utmost importance that only those varieties of food should be administered which did not coagulate in the stomach, and which did not readily undergo acid fermentation or stimulate acid secretion. Perhaps the best form of food was whey, fortified with an emulsion of butter or some other convenient form of fat. The introduction of coagulable varieties of proteid, such as the caseinogen of cow's milk, must be carefully graduated, and follow on Nature's

Dr. Pritchard then proceeded to explain some of the points in the rational treatment of the symptoms of vomiting, diarrhoea, colic and constipation. In vomiting, he remarked that it was important

to distinguish whether the symptom was due to over-stimulation or over-filling of the stomach, or whether it was due to the mere formation of a habit. Over-stimulation was usually due to the too rapid formation of the clot of caseinogen, or to the production of an excess of acid. Over-filling was often due to incomplete emptying and pyloric

The treatment of cases of acute diarrhoea was so simple and straightforward that he was surprised so many methods were employed. The first step was to suspend food altogether for twelve hours or longer; the second, to irrigate the colon as high up as possible with hot water enemata (the water should be of a temperature of about 103° F., and plentifully employed); the third step was to administer diffusible stimulants (brandy or ammonia) and opium by the mouth. It was quite astonishing how rapidly the symptoms disappeared if this line of treatment was adhered to.

Colic, Dr. Pritchard remarked, was generally due to dys-peristalsis, and the dys-peristalsis was often caused by local congestion, or the tearing off of small pieces of mucous membrane. The motions should always be carefully washed out and examined for little balls of rolled-up mucous membrane. From a practical point of view, the best form of treatment for colic, after the urgent symptoms had subsided, was ipecacuanha wine and elixir of papain.

The treatment of chronic constipation should not be that of aperients or laxative drugs; far the best line of management was massage, combined with large and continued doses of petroleum emulsion. Petroleum, unlike animal or vegetable oils, could not undergo decomposition in the bowel, and thus lead to toxic symptoms; it could not be absorbed, and hence it reached the lower parts of the bowel, lubricated it from end to end, and softened the motions. Persistent and methodical training in regular habits was, of course, an essential element for success.

# THE ARREST OF MAMMARY SECRETION.

BY ARTHUR J. WALLACE, M.D.,

Hon. Surgeon, Hospital for Women; Hon. Hospital Medical Officer Ladies' Charity and Lying-in Hospital, Liverpool.

THE arrest of the secretion of milk may appear a trifling subject to write about, even shortly, but it is one of those little points of detail that are apt to receive scant attention. The secretion of milk is no exception to the law of supply and demand, and in many cases, when there is no demand, the secretion lessens and disappears without treatment of any kind whatsoever. But there are others in which some treatment is requisite, and the methods usually employed include restriction of fluids and diet, internal administration of saline aperients, of belladonna or atropin, and of potassium iodide; whilst locally the treatment has consisted in firmly bandaging the breasts or applying belladonna in some form. These methods are, no doubt, quite useful in the majority of cases, though even there they have their drawbacks, whilst in a minority of instances they altogether fail. Dissatisfaction with them led me some years ago to seek for some remedy that would act surely, without discomfort to the patient, and which would render superfluous local treatment of all kinds.

The starting-point was the developmental affinity of the mammary gland with the glands of the skin. What reacted on the latter would probably produce some effect on the former-the reason, of course, why belladonna and its alkaloid have been so much employed. After a little search, agaricus albus was tried in the form of the tincture. It proved to be very efficacious in the first case in which it was used, so a more extended trial was made as oppor-tunity offered. Since that time it has been given in many cases, both in hospital and in private practice, with satisfactory results in every case (one exception has occurred lately; of this more anon), so that its usefulness seems to deserve a wider recognition.

Agaricus albus (white agaric, purging agaric) receives little or no notice from text-books of materia medica. According to Martindale ("Extra Pharmacopœia," 12th ed., page 725) the dose of the powder is from 10 to 30 grains, that of the tincture from 20 to 60 minims. He states also that the drug is used in small doses to check night sweats, to control diarrhoea, and to diminish bronchial secretion. In large doses it is said to be a purgative. It is also pointed out that the agaricus albus should not be confused with the fly agaric, amanita muscaria, a homoeopathic remedy employed, I believe,

for chilblains, &c.

My experience is limited to the Tr. Agarici albi, given in doses of from 30 to 40 minims in water, thrice daily, for the purpose of arresting the secretion of milk. This arrest is brought about gradually without any unpleasant symptoms or any local mammary disturbances, and without the application of local treatment of any kind. Given in cases in which the secretion has already become well established, there occurs a steady diminution in the amount of milk, until in the course of a few days it will be found that the breasts have become soft and flaccid, and that secretion is practically at an end. At the same time the skin of the body generally becomes dry, particularly that portion adjacent to the mamma and in the axillary region.

In cases of still-birth, the drug has been commenced on the day following delivery. Sometimes no secretion of milk has occurred; in other instances small quantities of fluid ooze through the nipples for two or three days, the secretion then quietly and unostentatiously disappearing. Bandaging has been used in such cases as an additional aid, but as it appeared to be unnecessary it was discontinued, and reliance is now placed wholly on the drug.

The only instance in which the drug proved unreliable was in the case of a patient who, according to her family doctor, reacts in a most surprising and unexpected manner to most drugs. The administration of agaricus was followed in this case by vertigo, so its use was at once stopped.

Whether agaricus might be useful in galactorrhœa I cannot say, as I have no experience of its use during the actual continuance of lactation. Possible effects on the infant call for caution under such circumstances

#### ON THE

# PATHOGENY, DIFFERENTIATION, AND TREATMENT OF GOUT.

By S. A. ARANY, M.D.,

#### PATHOGENY.

ALTHOUGH gout has been known long ere the Christian era, no scientific explanation of its pathogeny was offered until Garrod's time. The first step into the mystery of the causation of gout was taken by this scientist, who, with his scanty methods, established the theory that there is an excessive formation and insufficient elimination of uric acid, accompanied by reduced alkalinity of the blood and impaired function of the kidneys in gout, which is even nowadays the starting

point of all theories.

The excessive formation of uric acid, as well as the reduced alkalinity of the blood and the impaired condition of the kidneys, have been refuted by several authors, and Klemperer (1) was successful in proving that Garrod wrongly considered the gouty blood to be overcharged with uric acid, as, according to Klemperer's investigations, it was able to dissolve an additional amount of uric acid, and he also found that the alkalinity of blood was only reduced in solitary cases. Minkowski (2) also excludes the possibility of an excessive formation of uric acid, and presumes only a retention of uric acid caused by some functional disturbance of the kidneys, which view is fully shared by v. Noorden, but which is opposed by Ebstein (3), who is in favour of an excessive formation of uric acid. So far it could not be proved which of these views is correct, but since we know that the excessive formation of uric acid is not only peculiar to gout, but is also met with in Bright's disease and leukæmia, in which, however, no gouty symptoms are traceable, it is of however, no gouty symptoms are traceable, it is of secondary importance whether the formation of uric acid is, in fact, increased. The excessive formation of uric acid in Bright's disease was already known by Garrod, but he was unable to account for it. The excessive formation of uric acid in leukæmia was investigated by several authors, and Magnus-Lewy (4) found the greatest amount of uric acid, the latter amounting to 22.6 mgr. in 100 ccm. of blood. The excessive formation of uric acid in leukæmia is either due to the decay of an increased number of leucocytes or to the accelerated process of assimilation produced by the increased number of leucocytes (v. Leube, Deutsche Klinik.), and is, in spite of the fact that its extent largely exceeds the amount of uric acid present in gout, unable to produce gouty deposits. This also proves my investiga-tions in two cases of leukæmia, in which I tried Garrod's test, and although the blood-serum contained 9.5 mgr., and 8.5 mgr. of uric acil respectively, no crystallisation of urates could be effected, whereas in cases of gouty blood no negative results were experienced.

As the presence of excessive uric acid in the blood is not enough to account for the causation of gout, the authors directed their attention to the kidneys, presuming that only a retention of uric acid caused by some kidney disorder is apt to produce gout. Lewison (5) investigated the metatarso-phalangeal joints in 42 cases of kidney disease, and found in 12 cases deposits

of urates in the joints, and granular atrophy in the kidneys, whereas in the remaining cases no deposits of urates and only other kinds of kidney disorders could be established; from which he draws the conclusion that only the granular atrophy of the kidneys is able to produce gout, and, according to his opinion, it is not absolutely necessary to find visible changes in the kidneys, as the causation of gout is only due to some functional impairment of those organs. In centrast to Lewison's cases, Minkowski mentions six cases of granular atrophy of the kidneys in which no deposits were found in the metatarso-phalangeal joints, and refers to his experience, which I also fully endorse, to the effect that he has had gouty patients a great many years under his care, but never had a single case in which there was a kidney trouble diagnosable. Ebstein (1.c) mentions two post-mortems of gouty cases with normal kidneys, which, however, does not prevent him from considering a granular kidney with no deposits in it a gouty kidney; in his opinion a certain noxiousness, as in lead poisoning and in alcohol, must also be present in gout to account for the induration of the kidneys.

However, the noxiousness to which Ebstein ascribes the induration of the kidneys may, in my opinion, be looked upon as the producer of gout itself, in favour of which theory are those cases of gout in which no renal changes are detectable. Besides, it is far from ascertained whether the renal changes, if present, are the primary lesion or are only a symptom brought on by the producer in the course of the disease, and Lewison's results are by no means conclusive, as everybody will admit that there are many pathological changes, the clinical symptoms of which never were detectable intra vilam, and, on the other hand, the clinical symptoms of many a case are not justified by

the post-mortem.

But, even if there are pathological changes in the kidneys, are we entitled to consider these organs the source of the disease? as the cases of post-mortem examinations are very advanced cases of gout, in which there are renal and other changes, as a rule; and, on the other hand, they are counter-balanced by a large number of cases with no pathological changes in the kidneys, and if we are to presume in these latter an undiagnosable kidney trouble, we should be guilty of the same mistake as the supporters of the renal diabetes, of which I made mention (6) in my treatise, "On the Pathogeny of Diabetes."

We cannot and must not acquit ourselves of the fact that certain noxiousnesses, as alcohol and lead, render the constitution more prone to gout, and if we take into consideration that these substances produce a toxic influence upon the constitution, we are justified in supposing that in cases in which such noxiousnesses are not traceable, there must be another toxin which is responsible for the causation of the disease. There is even no necessity to suppose one special toxin as the producer of the disease; the latter can possibly be brought on in one case by one toxin, and in the other research we another toxic influence. Besides, we cannot

case by another toxic influence. Besides, we cannot consider it a fail accompli that the disease which, according to present-day conception, is styled gout, is a uniform disease, and future research may prove that gout, which is known to us by its symptoms only,

is brought upon us by various influences.

How far the abuse of alcohol may be instrumental in giving rise to gout can be best judged by taking into consideration the frequency of gout in different countries. Very instructive is Rendu's (7) report, according to which gout is very rarely observed in Spain, France, Italy, Turkey, and Greece; more frequently in Germany, Denmark, Sweden, Norway, and Russia; and the most cases come in England and Holland under observation. Taking the first group of countries into consideration, we see that they are, with the exception of Turkey, wine-consuming countries; the second group is inhabited by peoples consuming partly beer, partly concentrated liquors; finally, the last group represents the greatest consumers of liquors—viz., whisky, brandy, and liqueurs. One must, therefore, arrive at the conclusion that the different kinds of alcohol act differently upon the constitution, and that wine seems to be the least detrimental in contrast to spirits, which render the constitution most

prone to gout, especially in countries like England, where, besides spirits, a great deal of meat is consumed. We must maintain this view, even in the face of Herter and Smith's (8) investigations, according to which whisky contributes less towards the increasing of uric acid than champagne, as Rosenfeld (9) has proved, beyond doubt, that alcohol greatly increases the formation of uric acid by favouring the decay of the nucleins.

It is also a very well-known fact that people who have gone through rheumatism show a certain predisposition to gout. and even if we do not concur with Duckworth's (10) view that gout and rheumatism are only branches of one and the same disease, we shall have to consider a rheumatic history a possible agent provocateur of gout.

Whether all these noxiousnesses mentioned can be regarded as the producers of the diseas: itself, or whether they only favour the action of a specific gouty toxin, must be left unanswered, but one fact holds good that the uric acid itself cannot be the producer of the

Minkowski's supposition that uric acid is, under normal conditions, combined with nuclein acid, and can only in such combination be excreted by the kidneys, is, in itself, also insufficient to explain the causation of gout, as supposing the normal blood contained the combination of uric acid, suggested by Minkowski, a special influence would be required to change the normal combination of uric acid into an abnormal one.

Still less comprehensible is Ebstein's theory without the supposition of a gouty toxin; this author is of the opinion that the primary lesion is the faulty condition of the protoplasm and of the nucleus of the cell, owing to which uric acid, as well as other aloxur and nuclein bodies are formed excessively, and perhaps on the wrong place. Under normal conditions, the uric acid found in the muscles and bone-marrow is loosely combined with alkali, a part of which is being decomposed ere leaving the system, and the other part gets eliminated by the action of the kidneys. Now, if there is an excessive formation of uric acid in those organs and a hindrance to the decomposition and elimination thereof, gouty symptoms will ensue.

If we confront the individual theories of Minkowski and Ebstein we find, not taking into account that the first is not, and the latter is, in favour of an excessive formation of uric acid, a contrast between the two, as Minkowski supposes, a decomposition of the normal combination, whereas Ebstein is in favour of an insufficient decomposition of uric acid in gout. Nevertheless, both theories may lay claim to plausibility if we consider them as brought on by the influence of a toxin which in the one case transforms the soluble combination of uric acid into a combination which is not soluble in the blood; and in the other case the toxin may be regarded as the destroyer of the substance which is instrumental in decomposing the uric acid.

My presumption is confirmed by v. Noorden, who does not exclude the possibility that besides the uric acid a special toxin may be instrumental in prducing gout, and he adds that it is very likely that the uric acid is only formed in the diseased tissues, and owing to the chemical peculiarity of the process it cannot get dissolved and eliminated.

However, Ebstein himself is not quite certain whether he should entirely ascribe the production of gout to the uric acid or to an unknown poison, which may assist the former in its action.

Without the assumption of a toxin it would also be impossible to comprehend Ebstein's theory about the causation of tophi, according to which the inflammation and necrosis of the tissues precede the deposits of urates, and, therefore, we are justified in supposing that the former may be brought on by the toxin, and in the same way must be produced those gouty inflammations with no or very little deposits, and we shall have to regard the uric acid as the product of the gouty toxin, which in the course of the disease gives rise to various pathological changes of the

What kind of toxin could be blamed for the causation of gout is a question which must be left open, although a toxin of bacterial origin analogous to that of gonorrheal arthritis may come into consideration, but, on the other hand, there is nothing to prevent usfrom supposing a toxin of endogenous origin produced by the system itself to be the producer of gout.

FEB. 17, 1909.

Even if we ignore the origin of the toxin, we are entitled to suppose that it chiefly affects the assimilation of the nucleins by either increasing the formation and changing the chemical combination of uric acid, or by changing the combination of uric acid only. The toxin also seems to possess the ability of producing inflammatory processes in the various organs in which, as a matter of course, urates get deposited.

my innamiatory processes in the various organs in which, as a matter of course, urates get deposited. The theory of a gouty toxin does not exclude heredity, which is recognised by every author, and I have to repeat here the same said (12) about the heredity of diabetes, viz., that the disease as such cannot be inherited, it is only a certain predisposition for gout, which can be transmitted from parent to child. Nor does the theory of a toxin interfere with other ætiological factors as high living, lack of bodily exercise, abuse of alcohol, and certain occupations which can possibly render the system more prone to the influence of the toxin.

As we have seen, one part of the authors does not exclude the possibility of a toxin, but at the same time-they seem to recoil from their own presumptions, trying to substitute the same partly by the abnormal condition of the protoplasm, partly by some undiagnosable kidney disease. As long as the greatest masters of research will be haunted by the idea of an undiagnosable kidney trouble, and as long as gout will not be considered from a bacterio-chemical point of view, it will not be possible to ascertain the producer of gout, and only research in the before-mentioned direction has a prospect of success

DIFFERENTIATION.

The various authors proposed, according to their individual theories, different classifications. In my opinion gout can be classified in two directions—viz., according to the origin of the uric acid and according

to the clinical symptoms of the disease.

In order to explain the differentiation in the first-named direction, we have to consider Fischer's (13) and Miescher's (14) investigations, according to which the human system possesses the ability of forming uric acid of the pre-formed purin-bodies of the food ingested, which purins originate from a combination of nuclein-acid and the albumens contained by the nucleus, chemically styled nucleo-proteils. On the other hand the system also possesses the ability of forming uric acid by the breaking down of its own bodily cells, which process is styled by Burian and Schur (15) as the endogenous formation of uric acid in contrast to the former process, which is called the exogenous formation of uric acid.

Now everybody who had a great number of gouty patients under his care will admit that there are certain cases in which a purin-free diet will not only improve the uric acid condition of the blood, but will also prevent future attacks. On the other hand, cases must be mentioned in which the withdrawal of purins, and even the severest restriction of nitrogenous food, does not produce any appreciable improvement, and Minkowski calls attention to the fact that, under certain conditions, the comparative ratio between uric acid and urea can become much lower if the restriction of nitrogenous food is too severe, than on an unrestricted diet, which is due to the fact that the severe restriction increases the breaking down of bodily tissue—i.e., the formation of uric acid.

According to the origin of uric acid I therefore propose to classify gout into—(1) exogenous or alimentary form of gout, and (2) endogenous gout.

Garrod and his followers distinguished, according

Garrod and his followers distinguished, according to the clinical symptoms, two kinds of gout—(1) the regular or articular gout, and (2) the irregular or internal gout, which distinction is, in my opinion, quite unjustified, as we have no right to consider the gout of the internal organs as irregular, in contrast to the articular gout; moreover, both kinds can be regarded as regular or irregular, as a disease which attacks the

whole system does not produce its anatomical changes according to rules.

Riess (16) calls the articular gout the acute form, in distinction from the internal gout, which he terms as chronic, retrograde, or metastatic gout. It is hardly necessary to point out how erroneous this distinction is, as everybody must be away of the fact that both kinds may be acute and chronic.

Embodying his own theory, Ebstein (l.c.) distinguishes the primary articular gout from the primary renal gout, and, as we have seen in the pathogeny, Ebstein's theory is far from proved, and therefore it cannot serve as a starting-point for the differentiation

of gout.

Taking the clinical symptoms of gout into consideration, I propose the following differentiation:—(1) The articular gout, showing symptoms of a more or less localised character; and (2) universal gout with or without articular symptoms.

The universal gout is usually the later stage of articular gout, but it may also attack individuals, who never had localised articular gout, and is apt to attack any organ without necessarily producing articular

symptoms.

Dealing with gout, I consider it opportune to mention a series of cases of my observation in which gout and nephrolithiasis, and vice versa, were combined. I feel the more justified in doing so as a number of authors claim that there is no connection between the Trousseau was the first who pointed out that the above ailments are one and the same disease, and only attack different parts of the body, and, according to either theory of gout, it is quite doubtless that the urolithiasis is only a kind of gout. In favour of this speak Hubbard's (17) reports to the effect that gouty kidney produces the same kind of nephralgia as is experienced in nephrolithiasis, and very satisfactory is the explanation offered by Minkowski, who considers the deposits of urates in the kidney the starting-point of a renal calculus, which, if liberated, gives rise to nephrolithiasis. Highly conclusive are also my own observations to the effect that 22 cases of typical gout were accompanied by nephrolithiasis, the latter being proved by gravel and calculi of various sizes; and then I have to report 18 cases of nephrolithiasis in which either typical joint-attacks or tophi were observed, the 18 cases of nephrolithiasis being one-third, and the 22 cases of gout about one-fifth of my cases of nephrolithiasis and gout respectively.
TREATMENT.

It goes without saying that an ailment for the pathogeny of which so manifold and contradictory explanations are offered, cannot have a uniform therapy, and as the healing factors suggested by the various authors are more than legion, it would be waste of time and space to consider them all. We shall, therefore, confine ourselves to healing methods the efficacy of which is objectively proved, or which are recommended by empiricism founded on huge experience, and shall start with

shall, therefore, connie ourselves to healing methods the efficacy of which is objectively proved, or which are recommended by empiricism founded on huge experience, and shall start with

The Dictary.—In the cases which I style the exogenous or alimentary form of gout, the dietary is the only healing factor to be considered, and it will be our duty to exclude all purin-containing food from the diet. Various researches, and especially those of Weintrand (18), have proved it that the nucleary organ—e.g., thymus, liver, spleen, and brain—greatly increase the formation of uric acid, and can be regarded as the chief producers of exogenous uric acid. Besides these organs, animal food in general is looked upon as a uric acid-increasing factor, and we know by Strauss's (19) researches that it is chiefly the extractive principles of meat which contribute towards the formation of uric acid, which fact may be utilised dietetically. It is a well-known fact that meat loses more of its extractive principles by boiling than by roasting, and therefore boiled meat will do the gouty patient less harm than roasted, whereas the soup in which the meat was boiled is unfit for the consumption of a gouty individual.

It has been extensively discussed whether the different kinds of meat act differently upon the formation of uric acid, and Kaufmann and Mohr (20) endeavoured to decide this question by experimenting with the different kinds of meat, and found that beef, veal, and fish equally contribute towards the formation of uric acid. Although it is not my intention to diminish the scientific importance of these experiments, I cannot help saying that, according to my own experience, gouty patients do much better if their meat supply consists of the so-called white meats. This experience of mine may also be due to the fact that the latter kinds of meat are more easily digested than the black meat, but, even if it were so, I think the preference ought to be given to the white meat, as the digestive organs of gouty patients are, in the majority of cases, also affected. Mention must also be made that the last-named authors found that eggs do not increase the formation of uric acid, which is, taking into account the high nutritive value and extensive use of eggs, of the utmost importance.

Fat, especially in the shape of butter, is recom-mended by Ebstein as a useful addition to the food, as, according to his experiments, doses of 120 grammes per diem do not increase the uric acid. He also recom-mends to substitute the carbo-hydrates by fats, as the former give rise to indigestion. I personally cannot concur in Ebstein's opinion, and think that the exclusion of carbohydrates in preference to fat-stuffs is more likely to cause indigestion. This I know by my vast experience in diabetic cases, and although Minkowski's argument in favour of Ebstein's prohibition is that no food-stuff is so easily misused as the carbohydrates. I cannot see my way to withdraw this purin-free food from gouty patients. On the other hand, there is no doubt that an excess of carbohydrates may also be instrumental in doing harm, but it is our duty to prevent the patient from excesses of any kind, and to give him just the amount of calories required by his system. Therefore, I should never think of giving a patient more or less than 35 calories per each kilo of bodily weight (excepting the acute attack of gout), and even Ebstein admits that anything producing a weakening effect upon the constitution is apt to do the patient

Even the fact that we have to restrict the consumption of meat is an indication not to deprive the gouty of the carbohydrates, and the easily digestible green vegetables, salads, potatoes, and the indispensable bread, are very welcome additions to the diet, whereas the cereals, the dry leguminosæ, cucumber, tomato, and sweets can easily be dispensed with.

The noxiousness of alcohol has already been pointed out, and the gouty subject is best advised to abstain from alcohol in general. However, not in every case shall we be successful in attaining total abstinence. Besides, there are also cases in which the total restriction of alcohol is contra-indicated, in which cases we shall have to allow a pint of light wine, well diluted with mineral water, or one to two glasses of Pilsen beer per diem. English practitioners permit a small amount of old whisky, with plenty of water, which is, according to Herter and Smith's investigations, less detrimental than champagne. Our view about spirits las been pointed out in the pathogeny, and we only want to add that, owing to the greater concentration of alcohol, spirits are more easily taken in excess than any other kind of alcohol, and are, therefore, best prohibited.

Among the other popular drinks, coffee and tea have to be considered, the first of which, although its noxiousness has so far not been proved, I usually exclude from the diet, as my experience has taught me that the clinical symptoms of gout are detrimentally influenced by coffee. Weak tea and cocoa seem not to interfere with gout, but the most suitable beverage for gouty people is undoubtedly milk, which I also (23) employ as the only article of food during the acute attack of gout, in spite of Cantani's (22) apprehensions that the lactic acid contained by the milk is apt to reduce the alkalinity of the blood, which neither Cantani nor others were successful to prove. As far as the products of milk are concerned, butter has already been mentioned, and, with regard to cheese, we usually avail ourselves of different kinds of cream cheese in preference to strong cheese. The latter, as well as spices, spiced sauces, and preserved food, are unsuitable for gouty subjects, and I was told by many a sufferer that, according to his own experience, the hors d'œuvre and the dessert are the chief sources of his attacks.

Last, but not least, we have to bespeak the water, which may be freely consumed by the patient, and if there are no contra-indications on the part of the circulatory organs and the kidneys, it will be advisable for the patient to take large quantities of water so as to effect a washing-out of the system. This purpose is served best by the alkaline table waters— $\epsilon.g.$ , the Biliner and Giesshübler waters.

Having considered all the articles of food, it only remains to make practical use of them, and in so doing we must consider one fact—viz., that moderation in every respect has to be the chief feature of the gouty patient's diet. We shall not recommend him more than three meals daily, and shall give him for breakfast a cup of weak tea or cocoa, or a pint of milk, two eggs, and bread and butter; his dinner will consist of soup (with the exception of broth and beef tea), 200 grammes of meat or fish (preferably boiled), green vegetables, stewed fruit, a light and not sweet farinaceous dish, cheese, fruit, and half-a-pint of light wine, with plenty of water. The evening meal, which must not be taken too late, may consist of 100 grammes of ham or cold fowl, eggs in every shape, to which one may add plenty of vegetables, cheese, bread and butter, and fruit, and, as a change, porridge or rice may also be made use of.

Whether dietary has any influence on the formation of endogenous uric acid has not been decided satisfactorily, but, as dietetic measures certainly improve the clinical symptoms of gout, we are not wrong in supposing that a suitable diet is also apt to reduce the

formation of endogenous uric acid.

The Medicinal Treatment refers to a great extent to the acute attack of gout, and is, in spite of the fact that latterly quite a number of "uric acid dissolving, combining, or eliminating" drugs have been recommended, by no means more advanced than twenty years ago, as all of these specifics of gout have failed to prove their specific action, and one feels compelled to return to the older drugs. Amongst these we gladly avail ourselves of the iodide of potassium, or of its newer and less disagreeable substitute, the sajodin, of which drugs one usually prescribes from 2 to 3 grammes per diem. Very effective are the salicylates, and especially the aspirin and its varieties, the nov- and diaspirin and salol, which increase to a large extent the elimination of uric acid. In what way this is performed is not established, but, in my opinion, it is very likely that it is the antiseptic action of the salicylic acid contained by these preparations to which the improvement is ascribable. The same refers to the good results obtained by urotropin, in which drug the antiseptic action of its chief component, the formaldehyd, has to be considered. In cases of long duration it will be advisable to use the drugs so far mentioned alternatively, and it will be quite safe to prescribe from 3 to 4 grammes per diem of any of them. In very painful cases we may add small doses of antipyrin. phenacetin, or pyramidon, or still smaller doses of opiates to the salicylates, but it is advisable not to be too generous with the former.

English doctors have a decided liking for colchicum, although the salicylates exceed its action by far, and do not prove so frequently detrimental to the heart as the former.

The alkalies deserve special consideration, and although their action upon the gouty system is far from ascertained, the authors gladly take refuge in them if all the other drugs have failed. Most popular are the natural alkaline mineral waters containing the various kinds of alkali in judicious concentrations, which renders them most convenient for the purpose. The purgative action of these waters is also of great importance, and whether their temperature does not produce special osmotic changes is a question which has to be considered. In the case of the Carlsbad waters we shall also have to consider their radioactivity, which is, as we know, a healing factor of great importance.

It is also customary to prescribe baths in gout, and for this purpose warm baths are recommended in preference to cold ones, as the latter are not well tolerated by the patient. The same refers to excessively hot baths, which also prove detrimental to the ailment, whereas for local applications both cold and hot com-presses can be considered.

Of the greatest importance is bodily exercise, which is, excepting the acute attack of gout, when the patient is best confined to bed for a few days, just as important a part of the treatment as the dietary and medication. There is no doubt that walking is the best kind of exercise, but also the various sports, if connected with walking, may answer the purpose.

# OPERATING THEATRES.

GUY'S HOSPITAL.

INTERSTITIAL HERNIA. - MR. R. P. ROWLANDS operated on a stout publican, who had worn a truss for double inguinal hernia for many years. He attended a public dinner three days before operation. Soon afterwards several of his companions were seized with abdominal pain and vomiting, but the patient remained well until the next morning, when he had diarrhoea. The bowels were opened three times in quick succession, and each time the ruptures came down and were as frequently replaced by the patient himself without unusual difficulty. The right one was not seen afterwards, although the left descended several times when the truss was off. Upon returning from business in the evening, the patient was taken with shivering, vomiting, and collapse. The vomiting persisting, Dr. Jaynes was called in. At first the pain was general all over the abdomen, but towards the evening it became localised to the right iliac region, where a tender region, where a tender swelling appeared and rapidly increased in size. The vomiting continued, and the bowels were not moved after the next morning, although a good deal of flatus was passed. The temperature was raised, and the pulse became increasingly quick. On the third day after the seizure Mr. Powlands saw, the potient in consultation with Mr. Rowlands saw the patient in consultation with Dr. Jaynes. At that time the abdomen was distended, but fairly supple, except on the right side, where it was rigid and tender. A large oval swelling occupied the appendicular region, its long axis passing downwards and inwards nearly as far as the middle of Poupart's ligament. This swelling was resonant in front, but dull at the side; it fluctuated and gave a succussion splash; it seemed to be too prominent for an appendicular abscess, containing gas. Rectal examination revealed nothing more than some bulging due to increased abdominal pressure. An enema was given, without result. A little fluid was discovered in the right hernial sac, which was within the scrotum. The

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE. CLINICAL SECTION.

MEETING HELD FRIDAY, FEBRUARY 12TH, 1909.

The President, Sir Thomas Barlow, Bart., K.C.V.O., in the Chair.

Mr. Butlin exhibited his collection of drawings of EARLY CARCINOMA OF THE TONGUE and of conditions which may be mistaken for it; and spoke of the results of the operations which had been practised in the cases exhibited. Microscopical sections of the cases were on view. He said that recently the *British Medical Journal* had published for him a series of 197 operations for cancer of the tongue. Since then he had had 3 more, bringing his total up to 200. Another journal, commenting upon this paper, had said that this number seemed so small, and that other surgeons must have performed very many more. Mr. Butlin contested this, and said that as far as he could determine no Continental or American surgeon whitehead was the only surgeon who had operated upon more cases than himself. Dr. Tatham, from the Registrar-General's Office, had informed him that 5,253 persons died from cancer of the tongue from the control of the control of the tongue from the control of t 1901 to 1907, makin gan annual average of 750. Allowing generously for recoveries as the result of treatment, this meant that probably about 820 persons suffer in England every year from this disease. The bad prognosis, in operations for this disease, had drawn his attention to the importance of early diagnosis, and treatment, so that he had at one time described a precancerous stage, but had found great difficulty in getting operations, both from the patient and his doctor, while he himself was unable to declare decidedly that cancer was present. Five years ago he had sent to Dr. Bashford material from a "precancerous" condition, which had proved to be well-marked carcinoma. Afterwards he had had careful drawings made of all such cases, and had insisted upon operation. From this collection he could separate five classes of early cancer of the tongue:—(1) A little plaque, like a hard sore, smooth and polished, but neither ulcerated nor excoriated. (2) The transformation or replacement of a simple ulcer by a cancerous ulcer, which only differs from the simple ulcer by feeling a very little stiffer and firmer. (3) The transformation of an entire plaque of leucoplakia into a plaque of cancer. The dif-ference was marked by a very slight thickening, a denser white, and furrowing or fissuring in various directions, but without excoriation or ulceration. The transformation of one small area of leucoplakia into cancer, only marked at first by very slight super-ficial hardness. (5) A white warty growth or com-pound wart, not ulcerated, feeling as if it were fixed in the mucous membrane and quite superficial. These were the most frequent and typical varieties, but there were other less distinct forms.

Since he had had drawings made of these early stages, and had insisted upon operation, he had operated upon 14 cases, 12 of which were drawn. 3 had died-i of nephritis and cardiac failure, but without recurrence; r, four years later, from secondary affection of glands, 1 for which early operation had been refused. Eleven were alive and well, at periods of from 8 months to 41 years. No local recurrence developed in any of the 14 cases, although 8 had lived for from 3 to more than 4 years after the operation. The glands had been removed in 9 of the cases. The diagrams exhibited showed that the extent of the operation was generally out of proportion to the size of the cancer, but this was to remove the leucoplakia and chronic superficial glossitis.

There was one other point to which he would like to draw attention. "The air was charged with emanations of radium," which had been positively stated to cure early epithelioma of the tongue. Until recently, if he had been asked, he would have said that those who were best able to judge would have concurred in

patient was moved to Guy's Hospital, where an operation was performed by Mr. Rowlands without delay. Just before the operation the patient was rather col-Under general anæsthesia an oblique incision was made over the prominence of the swelling, the fibres of the external oblique were separated, and the cæcum was at once exposed extra-peritoneally. It was greatly distended with gas and some liquid fæces. Towards the inner part of the incision the hernial sac Towards the inner part of the incision the nermal sac was discovered and opened. Sanious fluid escaped, and the cæcum and appendix were seen to be congested and streaked with yellowish lymph. The obstruction was due to kinking of the cæcum upon the ascending colon at the neck of the hernial sac. At this point the cæcum had turned abruptly upwards and outwards round the lower border of the internal oblique muscle, upon the outer surface of which it The flexion was maintained by the pressure of the external oblique, which seemed to act almost like a strap. After drawing the cæcum downward and incising the lower border of the conjoined tendon, the hernia was then reduced and gas and pus escaped from the general peritoneal cavity, and lymph was seen upon the ascending colon and upon the ileum. A hand was therefore passed into the abdomen to seek a possible further cause of the peritonitis. The stomach, duodenum, gall-bladder, and pancreas were normal. It was therefore concluded that the peritonitis was due to the inflamed condition of the strangulated gut, and that leakage had occurred into the peritoneum through the wide neck of sac. The peritonitis seemed more or less limited to the right flank. The neck of the hernial sac was closed except for an interval for a large tube containing a wick of gauze. The lower part of the sac was drawn up from the scrotum and removed.

Mr. Rowlands said there was considerable difficulty in the diagnosis between appendicitis with a gascontaining abscess and reduction en masse of a right inguinal hernia. The absence of complete constipation as regards flatus, the unusual size and resonance of the swelling, and absence of history of pain or difficulty in reduction of the hernia, were much against reduction en masse. The swelling seemed to be unusually prominent and soft for a gas-containing appendicular abscess, but the general symptoms, the pyrexia, the early diarrhœa, and the later constipation, seemed to support this diagnosis. The presence of fluid in to support this diagnosis. The presence of fluid in the scrotal sac could easily be accounted for by either hypothesis, if the reduction en masse were considered to be due to laceration and not displacement of the sac. Interstitial hernia was, unfortunately, not thought The condition found at the operation was one of abrupt kinking of the ascending colon round the lower border of the conjoined tendon. There was no strangulation at the neck of the sac. The peritonitis was no doubt due to infection through the wall of the damaged bowel. It was difficult, he considered, to explain how the non-peritoneal part of the cæcum came to be in the sac; it was probable that the rupture had never been completely reducible, but that the cæcum had always been present in the interstitial part of the sac, to which it was congenitally adherent posteriorly.

In spite of active treatment by means of copious infusions of saline solution, and subcutaneous injections of ernutin, mx. every four hours, the patient gradually sank, and died two days after the operation. The bowels had acted several times. The post-mortem revealed hypostatic pneumonia and fibroid hypertrophied heart. There was localised peritonitis and a good deal of congestion of the lower part of the ileum and cæcum, but there was no perforation and no

Or the four general hospitals proposed for the London Territorial Force, the 1st, commanded by Lieut. Colonel H. M. Ramsay, F.R.C.S., is to be mustered this year for its first training at the Cambridge Hospital, Aldershot, and the 2nd, under Surgeon-Colonel C. Godson, at the Herbert Hospital, Woolwich. No arrangement has been made for the training of the 3rd and 4th London Hospitals, which, unlike the 1st and 2nd, have not yet attained the position of being officially recognised as units of the Territorial Force.

stating that there was no evidence to prove that radium was able to cure lingual cancer, and he would have added that the only case under his care so treated has ended disastrously. But, within the last few days, he had seen a case in which a typical epithelioma of the inside of the cheek had so much improved that it looked as though it would be quite cured. Radium, however, must act very differently from any therapeutic measure we at present understood, if it not only cured locally, but followed and eradicated the disease from the glands and intervening channels.

Mr. A. E. BARKER congratulated Mr. Butlin on his successful results. He had himself devoted attention to the pre-cancerous stage, and, when in doubt, had always extirpated the portions of the tongue affected. In only one case had cancer not been present. He hoped that the paper would stimulate all to increased activity in dealing with early suspected cases. He was not so sure that removal of the glands was always necessary, for undoubtedly many cases had recovered in which this had not been done. There were cases of very great and others of very low malignancy, and it was probable that some of the great successes were due to the fact that the surgeon was dealing with cases of low malignancy.

Mr. WALTER SPENCER thought that the small-celled infiltration which runs down between the muscle fibres should be taken as evidence of malignancy, and should indicate early removal of glands. Therefore the patch should be completely excised, and a microscopical examination made, before deciding on removal of the glands.

Mr. CLUTTON said that he was in absolute sympathy with all Mr. Butlin had said, both with regard to the removal of the growth and of the glands.

Mr. Bowlby had always removed the lymphatic glands, in all cases, with one exception. The patient had been unwilling in this case, and although that was eight years ago, there was at present no recurrence. He regarded this, however, as the exception rather than the rule. He had seen the patient referred to by Mr. Butlin as treated successfully by radium, but had not thought the case one of malignant disease.

Dr. Bashford said that one of the first discoveries that the Imperial Cancer Research workers had made, was that a very small piece of growth, even to the size of a pin's head, or less, could, by engrafting, reproduce all the evidences of cancerous growths, including metastases. He regarded Mr. Butlin's work as one of the first-fruits of the investigation. The growth was often spread out in a fan-shaped manner in the deeper structures, and this indicated a wider range of operation than apeared on the surface. New growth was modified by various constitutional changes, and these might take place suddenly and favour sudden dissemination. There was no means of telling how a tumour would behave from its intrinsic biological characters or from any constitutional symptoms which may arise.

Mr. Butlin, in reply, admitted that cases occurred which did not lead to metastases, but said that there was no method of distinguishing them, so that he did not consider it ever safe to leave the glands. He referred to a meeting of the Harveian Society, 25 years ago, at which the late Mitchell Banks had urged removal of the axillary glands in mammary cancer. This was now generally accepted, and he thought that the same would be true of the glands in cases of cancer of the tongue.

Dr. H. Morley Fletcher showed four cases of Oxycephaly.

CASE 1.—Male, æt. 21, assistant store-keeper; condition dated from early infancy. Intelligence good; vault of skull pointed; sagittal suture felt as a thickened ridge. Extreme proptosis; strabismus; globe of right eye was recently dislocated forwards as the result of a slight blow; patient was able to replace it under the lids himself. Mr. Holmes Spicer's report on the eyes: "Vision (with glasses) R.=6/36, L. sees only moving objects. Fundi: nerve fibres confined to upper and inner part of the opening in the sclerotic, probably due to an imperfect closure of the fætal cleft. The nerve fibres are also very pale, presumably due to primary atrophy. Both conditions more marked in the left eye." Defective formation of superior

maxilla; arch of palate extremely high; apex only just wide enough to admit tip of finger. Upper Jaw shortened; second and third molars absent on both sides, present in lower jaw. Antra practically non-existent. Naso-pharynx small in all dimensions (the deflection of the nose to the left is the result of an accident many years ago). His mother has proptosis and malformation of superior maxilla to a less degree, but her vision is good, and the cranial vault is of natural shape.

CASE 2.—Boy, æt. 13, Hebrew, very intelligent. Frequent headaches. Skull oxycephalic. Eyes: marked exophthalmos; left, external strabismus, nystagmus. Vision: could distinguish large objects. Fundi: double optic atrophy. Deformity of superior maxilla not so marked as in Case 1.

CASE 3.—Female, æt. 41, charwoman, intelligent, subject to occipital headache all her life. Skull oxycephalic. Proptosis and slight nystagmus. Vision: blind in left eye as long as she could remember; there was useful vision in right eye. Double optic atrophy.

The hard palate was asymmetrical and narrow. Case 4.—Boy, æt. 11. First child; breech presentation. Probably this case was closely related to the foregoing, but the characteristic shape of the vault of the skull was not present to the same degree. There was proptosis, but no nystagmus. Vision: R.=6/6, L.=6/9. No optic atrophy. The upper jaw was small and ill-developed.

He said that this rare deformity of the skull, otherwise known as "tower" or "steeple" head (lhürmkoff), generally came under the notice of ophthalmic surgeons, on account of the defective vision associated with the condition, and a large proportion of the recorded cases have been described in the transactions of ophthalmological societies. The cases exhibited the characteristic abnormally-shaped cranium, exophthalmos due to imperfect formation of the orbits, impairment of vision, the result of partial or complete optic atrophy, and varying degrees of malformation of the superior maxilla. There was no obvious defect of intelligence in any of the cases shown.

Dr. SUTHERLAND said that in some cases he had seen there had been a degree of mental defect.

The PRESIDENT said that the cases evidently came under the order described by Virchow as due to premature union of the cranial bones in various positions. The association of optic atrophy, he thought, a new point and one of special interest, and he would like to know how this was produced; was it by local overgrowth of bone pressing on the optic nerve?

Dr. Morley Fletcher, in reply, said that the condition was due to synostosis of the basis cranii and malformation of the superior maxillæ in his cases. The optic atrophy was certainly primary, and was probably due either to nipping of the optic nerve in the optic foramen, or to twisting of its course from maldevelopment of the basis cranii. All the cases of which he knew had shown a normal mental development

Mr. P. MAYNARD HEATH showed a case of DIFFUSE PERIOSTITIS OF BOTH TIBLE WITHOUT OTHER EVIDENCE OF CONGENITAL SYPHILIS.

Male, æt. 5, was brought with the complaint that his knees had been knocking together for three months, and that his shins had been swollen for one month. On examination, a slight degree of genu valgum was found. The skin of the front of the legs was slightly edematous and tender, and the superficial veins were dilated. There was a diffuse sub-periosteal thickening involving the length of the shaft of both tibiæ, most marked in the middle of the shaft and more on the right side than the left. There were no other signs of disease. The boy was one of a family of eight children, one of whom was under treatment for a tuberculous affection of the face at a London hospital, and another had been treated for a tuberculous knee at a provincial hospital (see next case); the others are The mother had not had any miscarriages, healthy. and no history of rashes, sore throat, or loss of hair could be obtained. X-rays showed diffuse deposit of new bone under the periosteum of both tibiz. As the result of treatment with mercury and potassium

iodide, the tenderness and cedema of the legs had disappeared.

Mr. P. MAYNARD HEATH also showed a case of CONGENITAL SYPHILITIC KNEE.

Male, æt. 3, brother of the previous patient, had suffered from a bad knee for twelve months, and had been treated for tuberculous disease of the joint with-Examination revealed some degree of left genu valgum, and that the inner side of the kneejoint was swollen and hot, the swelling lying chiefly over the inner tuberosity of the tibia. The synovial membrane felt thickened, there were a slight effusion in the joint, and some wasting of the thigh muscles. The bridge of the nose was broad and flat, but the boy did not have snuffles in infancy.

Dr. PARKES WEBER showed a case of CONGENITAL SPLENOMEGALY WITH CHRONIC ACHOLURIC

JAUNDICE.

The patient was a well-developed boy, æt. 14, somewhat anæmic and slightly icteroid. The spleen was evenly enlarged and hard, reaching to the anterior superior iliac spine. The liver could not be felt, and apparently was not enlarged; faces were not acholic. The urine was generally of rather low specific gravity, clear, pale, and free from albumin, sugar, and bile-pigment, but sometimes showed excess of urobilin. The blood serum was found to contain bile pigment, and when examined during the boy's most normal periods, showed a few normablasts and slight polychromatophilia. A blood-count on November 6th, 1908, gave 2,800,000 red cells, and 14,280 white cells to the cubic millimetre; the differential count of white cells gave lymphocytes, 20.6; intermediates, 4.8; large hyalines, 4.4; polymorphonuclears, 68.4; eosinophils, 1.0; mast-cells, 0.8 (no nucleated red cells seen on that occasion). A later blood-count (January 21st, 1909), gave 3,140,000 red cells and 14,500 white cells; hæmoglobin, 70 per cent. The resistance of the red cells towards hæmolysis had been tested on various occasions by Ribierre's method, and it is found that hæmolysis occurred when a few drops of the patient's blood, diluted with normal saline solution, were added to a solution of between 0.40 and 0.48 parts per cent. of sodium chloride in distilled water. There did not, therefore, appear to be much evidence that the chronic acholuric jaundice is "hæmolytic" in the present case, at all events, the evidence that it was due to congenital fragility of red cells was insufficient. Mr. Dudgeon found that the patient's blood-serum had no auto-hæmolytic action; nor had blood-serum from a normal individual any hæmolytic action on the patient's red cells.

The history was that he was born at full term with the help of instruments, and was very yellow at birth. The jaundice never completely disappeared; his eyes (sclerotics) had always presented a slight yellowish tinge, but his complexion had generally been sallow rather than distinctly yellow. He had been always subject, however, to recurrent attacks of "depression," during which his urine became darker and he appeared yellower, and he suffered from lassitude and drowsiness. These attacks occurred about every three months and lasted a few days. Sometimes he suffered from severe abdominal pain. He had never had any form of hæmorrhage, excepting a mild attack of purpura in 1899, when he was 4 or 5 years old, at which time the blood contained many nucleated red cells. His spleen was apparently first noticed to be large when he was 3 months old. He had always been subject to nocturnal enuresis. He had had no other illnesses ex-

cept "croup" at 1 year of age.

There was no probability of a congenital syphilitic taint. A sister, the twelfth of a family of thirteen, with anæmia and splenomegaly without any jaundice, died at the age of 1 year and eight months. Both she and the patient were shown in 1905, by Dr. Porter Parkinson, at the Society for the Study of Disease in A most interesting point was that the mother said that all her children were born yellow and remained yellow for three to six months after birth, but the jaundice was permanent in the present patient only.

Mr. R. HIGHAM COOPER showed a case of ADVANCED ACROMEGALY.

The patient, a man, æt. 51, stated that the enlargement of his extremities was first noticed in the great toes 17 years ago. His hands had always been unusually large. Changes in the ears and nose had begun 13 years ago, and the condition had steadily advanced. The size of the cranium was normal; there was enormous enlargement of the nose, ears, eyebrows, and upper eyelids, the latter hanging over the eyes so as to cause considerable limitation of the field of vision. He stated that he could not see out of his right eye, but the ophthalmoscope did not show any abnormality except slight pallor of the disc and blurring of the cup; there was no retinitis or hemianopsia. The malar bones were very prominent, but the superior maxillæ and upper teeth seemed normal; the mandible was prolonged forward so that the lower teeth were fully half an inch in front of the upper. The lower teeth were separated from one another by small intervals. Tongue was large, reddish, and furrowed with hypertrophied papillæ. There was enormous bulbous enlargement of the fingers, but the bones were free from the characteristic deformities. There was some general hypertrophy, but little change of texture or of their due proportion, and from the radiographic point of view they presented the typical characters of advanced gout; all the fingers showing deposits on the shafts of the phalanges, several with well-marked spurs, and one finger had two distinct excavations in the base of one phalanx and the head of the next. In the feet there was an entirely different picture; there was backward dislocation of most of the toes, and all the phalanges, except the terminals, had pipe-stem shafts with enormous "cauliflower-like" proliferation of the heads and bases, this proliferation being of a cancellous nature. Several attempts to take skiagrams of the sella turcica had been made, but without success. Skiagrams of the rest of the body did not show any special points of interest, except a gouty condition of the knees.

Mr. R. J. GODLEE showed a patient whose

FEET WERE DEFORMED BY GONORRHOBAL RHEUMATISM. The man, æt. 54, complained of pain in various joints, but was shown to the Section on account of the deformity of both feet, apparently the result of "gonorrhœal rheumatism" 29 years ago. The feet at that time had been simply bandaged. The soles were flat, the toes in the position of hammer-toe, and the ankles could only be flexed beyond a right angle after flexing the knees. All the joints of the tarsus and the metatarso-phalangeal articulations were believed to be in a condition of bony anchylosis. The spine was stiff and probably anchylosed. There was old iritis in both eyes and choroiditis in the left eye.

Mr. W. SAMPSON HANDLEY showed a case of ELEPHANTIASIS TREATED BY LYMPHANGIOPLASTY.

The patient, a clerk, set. 46, has never been abroad. The disease began in 1895 with swelling of the left testicle and pain in the left leg. The limb was moderately swollen and presented patches of erythema. Since that time he had been subject to recurrent pyrexial attacks, accompanied by erythema of the limb, which had steadily increased in size. On admission to the Middlesex Hospital in April, 1908, the left lower limb was enormously enlarged, especially below the knee. On the posterior aspect of the calf were two Another large mass occupied the dorsum of the foot. The patella could not be felt. The skin was much thickened, coarse, and rugose. Filariæ were absent from the blood. The first attempt at lymphane set plasty failed, owing to sepsis along the threads, set up by micrococci, which were present in the lymph previous to operation. Vaccine treatment was successfully applied to exterminate the infective cocci, and the operation was repeated on October 17th, 1908. The swelling of the limb rapidly subsided; within ten days the circumference of the limb just above the ankle fell from 21% in. to 12% in.; of the calf from 25% in. to 17 in.; and of the knee from 20 in. to 16% in. The subsidence had since continued less rapidly; the tissues had become soft and flabby; the skin thin and supple. The patient had now been back at work for some weeks, and there seemed to be every prospect

that the result of the operation will be permanent. This case—the first in which Mr. Handley's operation of lymphangioplasty had been applied to disease possessed more than ordinary interest, in view of the fact that elephantiasis had hitherto been considered incurable.

Dr. HERBERT P. HAWKINS exhibited a

CASE SHOWING TROPHIC CHANGES IN HANDS AND FEET, WITH ANÆSTHESIA (PROBABLY LEPROSY).

The patient, a girl, æt. 19, was born of English parents at Perambur, about three miles from Madras. About two miles from her home there was a leper She never came in contact with native children, but a native ayah was in attendance upon her for 18 months before any sign of disease was observed. Father, mother, and other children are healthy. The early history is not clear. Her father states that in 1803, she, being then four years of age, developed a "roughness" and "scabbing" on the knuckles of both hands. A native apothecary diagnosed leprosy, and prescribed a course of Chaulmoogra oil. From that time up to the present date the disease had made slow but uninterrupted progress. She had been in England since 1900. There was no dissociation of sensation. There was no perception of touch, pain, or temperature below the elbows and below the knees. Sensation was normal over face and trunk to all forms of stimuli. There was wasting of the intrinsic muscles of both hands, otherwise muscular nutrition was maintained. Muscular power was good; knee-jerks were rather brisk; no plantar reflex, and no ankle clonus, and no spasticity. Gait was normal. Skin of hands was rough and scaly, but by rubbing in ung. syno-cardiæ she had improved their appearance. There was a small oval patch on the right shin, where the skin was devoid of pigment. The ulnar and external popliteal nerves were not obviously enlarged. There were no enlarged glands and no joint affections. The fingers of the right hand showed a slow necrosis of soft parts and bones. Where a phalanx had been lost, remains of the nail were still perceptible on the stump. The left hand was in a similar state. X-ray examination verified this account, and showed also that a swelling of the second finger of the right hand was due to periostitis. The right foot showed a large ulcer on the ball of the great toe which began as a deep-seated blister. There was a smaller ulcer on the plantar surface of the left foot. No acid-fast bacilli were present in the discharge from the ulcers on the hands, and none were obtained from the nose.

Dr. F. PARKES WEBER showed a case of

CHRONIC SWELLING OF THE FINGERS.

The patient was a well-built, slightly anæmic-looking, unmarried woman, æt. 20. She complained of a persistent swelling or hard cedema of all her fingers. This had always been more or less noticeable as long as she could remember. There was some tendency to blueness of the hands and chilblains of the fingers in cold weather; and when she let her hands hang down they tended to get very red and sometimes blue, but there was no pain as in erythromelalgia. The swelling affected the soft parts of the fingers only, as shown by Rontgen-ray photographs. Examination of the blood showed nothing beyond slight anæmia. There was nothing remarkable in the family history. The case seemed to be allied to those of so-called "acro-

Mr. R. J. GODLEE showed a case of DERMOID CYST OF THE MEDIASTINUM TREATED BY OPERATION AND ILLUSTRATED BY A PATHOLOGICAL SPECIMEN.

This was the continuation of a case presented to the Clinical Society before operation by Mr. G. E. O. Williams and Dr. Batty Shaw, on October 27th, 1905. The patient was submitted to several operations in University College Hospital. In the first of them the lower part of the cyst was exposed by the removal of costal cartilages. The upper part was in such intimate relation with the large vessels at the root of the lung that its removal was impossible. Some portions of its inner wall and large quantities of hair were taken away. On subsequent occasions other portions of the skin lining the interior were cut away and cauterised. The result had been a considerable improvement in the general health and diminution of the expectoration. But a large opening remained in which the deep part of the cyst appeared, a forcible pulsation being transmitted to it by the action of the heart. There was a certain amount of discharge consisting of mucus and sebaceous material, with a characteristic offensive smell. There had been several attacks of hæmoptysis, in some of which a considerable amount of blood had been lost. Hardly any hairs were now produced

The specimen shown was one presented to the Museum of the Royal College of Surgeons by Mr. Thomas B. Mouat. The cyst, which was on the opposite side of the chest, presented many features of resemblance to that of the living case. The lower part was intimately associated with the pericardium. The upper was embedded amongst the large vessels of the

mediastinum.

The importance of considering the specimen in connection with the case was that it is possible thus to appreciate the kind of difficulty likely to be encountered in any attempt at removal of these particular cysts, which are in all probability teratomas.

Dr. Poynton showed a case of

AMAUROTIC FAMILY IDIOCY.

Female, æt. 9 months, had been brought to the hospital because she was unable to sit up; she had a dull and heavy expression, and was apparently almost blind. She was the second child; the first died at the age of 2 years and 4 months of what was called "water on the brain," but was clearly amaurotic family idiocy. Both parents were Jews, but were not related, and enjoyed good health. At birth she was apparently a normal infant, but since the age of 1 month had been noticed to be feeble in her movements; in the second month it was difficult to attract her attention with bright objects, and since then she had been going slowly down hill.

When exhibited she was very well nourished; expression vacant; skin of face rather greasy; possibly

could see a little; smiled frequently. Pupils, equal and rather large, reacted sluggishly; the fundi were quite characteristic. The limbs were very feeble, but not spastic, and there were no deformities. knee-jerks were present and the plantar response was extensor; the muscles appeared to be very flabby. The urine did not contain albumin or sugar. The particular points of interest were: (1) The early age at which suspicion was aroused; (2) the extremely well-marked changes in the fundi; (3) superficially the healthy appearance of the infant; (4) that the diagnosis of rickets had been made, as in three other cases under observation in the last four years.

Mr. L. COLLEGGE (for Mr. W. E. Fisher) showed a

patient illustrating

SPLENIC INFARCTION—SPLENECTOMY.

A married woman, æt. 47, the subject of mitral stenosis and visceroptosis, was suddenly attacked with pain in the left hypochondrium. On admission four days later there was a large tumour on the left side of the abdomen; the diagnosis lay between splenic infarction and torsion of the spleen. Splenectomy was performed the next day; the spleen contained two large infarcts and was adherent to adjacent parts. The patient left the hospital 25 days after admission. There was no anæmia and no glandular enlargements: 14 hours after a heavy meal the leucocyte-count showed

p,600, and 5 hours after a meal, 11,322.

Dr. H. MACNAUGHTON-JONES, JUN., demonstrated A SIMPLE APPLIANCE FOR OBTAINING, AND AUTOMATICALLY MAINTAINING ANY REQUIRED PRESSURE, ABOVE OR BELOW THAT OF THE ATMOSPHERE, WITHIN ANY CLOSED CAVITY CONTAINING AIR.

The apparatus, which might be appropriately termed a static pump, could be used for such purposes as exhausting an aspirator, cupping, or applying Bier's method of treatment. He first described its use with The apparatus consisted of a Bier's cupping-glass. two bottles of similar size and shape, each provided with two openings—one in the usual situation, and the other in the side of the bottle as near the bottom as possible. The lower opening in one was connected to the corresponding opening in the other by flexible tubing, and the bottles were half-filled with water. The upper opening of one was attached by tubing to the cupping-glass, whilst the other remained free. To facilitate description the former bottle was referred to as the "chamber," and the latter as the "receiver." the receiver was raised above the chamber, the water it contained flowed into the latter, filling it, and expelling the air which occupied its upper part through the tubing connecting it to the cupping glass. On lowering the receiver below the chamber the process was reversed. By raising or lowering the receiver, the water could be made to move up and down in the chamber like a piston, alternately drawing in and expelling air through the cupping-glass. If the receiver was lowered when the chamber was full, and the entrance of air prevented by the application of the cupping-glass to the skin, as the water descended in the chamber a partial vacuum was established and its flow arrested. The degree of vacuum depended upon the fall of water; if, e.g., the surface of the water in the chamber was 14 in., 28 in., or 56 in. above that in the receiver, the pressure in the former and beneath the cupping glass would be about 1 lb., 1 lb. or 2 lb. respectively, below that of the atmosphere.

Should a little air accidentally leak in beneath the

edge of the cupping-glass, as it usually does, it would simply permit of the escape of water until its flow was arrested by the establishment of the original vacuum. Thus by regulating the height of the fluid in one vessel above that in the other, the required pressure could be obtained and automatically maintained. precaution was necessary: the orifice of the lower opening in the receiver must always be covered by fluid, otherwise the pressure might fall below (the vacuum exceed) that which was intended.

In order to exhaust an aspirating bottle it was attached to the chamber precisely as the cupping-glass was; the chamber taking the place of the airpump or syringe at present employed for exhausting. If, however, any leakage occurred around the neck of the bottle, or in its connections, its extent would be rendered evident by the continued escape of water, and the degree of vacuum would be constantly known. When it was necessary to re-establish the vacuum in

the aspirating bottle without disconnecting it, the following manipulation should be carried out:—The tube connecting the bottle was furnished with a three-way cock. This might be used so as to bring the interior of the chamber into connection with the atmosphere, while cutting off the bottle. While in this position the chamber was filled in the usual way by raising the receiver; the tap was then turned so as to close both the bottle and chamber. The receiver was then lowered and the cock turned into its third position, in which it brought the chamber and aspirating bottle into communication again, while cutting off the atmosphere.

# ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, JANUARY 29TH, 1909.

Dr. PUREFOY in the Chair.

## MODIFIED INSTRUMENTS.

Dr. Ashe demonstrated a new principle for application to Bozemann's catheter and Braun's hollow sound by means of which every part of the uterus could be dealt with without fear of undue pressure. The instrument which he exhibited allowed all the fluid to come back, and with it the uterus could be flushed It was simple and cheap, and could be absolutely sterilised.

The CHAIRMAN considered that the instrument had a wide range of utility.

The SECRETARY spoke, and Dr. Ashe replied.

ADENO-CARCINOMA OF THE VULVA.

Dr. Solomons exhibited specimens of above. said that adeno-carcinoma of the vulva was such a very rare condition he thought the case would be of interest to bring before the Section. This he was able

to do by the kind permission of Dr. Tweedy, the

Master of the Rotunda Hospital.

M. W., æt. 33, married eight years, 4-para, was admitted in November, 1908, to the Rotunda Hospital. She had noticed a lump in the vulva two weeks before admission, and this ruptured just before she entered the hospital. Pruritus was absent. Patient was blanched from loss of blood. On examination it was found that there was a large stinking mass protruding from the vulva, which seemed to spring from inside from the vulva, which seemed to spring from inside the right labium, just at Bartholin's gland. The tumour was evidently an hæmatoma. On its removal an excavated sloughing sore came into view, which had all the appearance of acute phagedena. A microscopic examination showed nothing save blood clot. The cavity was plugged with iodoform gauze. Thinking that perhaps the affection was syphilitic, the patient was given a mixture of hydrare, perchlor, and potassium iodide. Insuffation with calonel was also potassium iodide. Insufflation with calomel was also used. Two weeks later, as there were no signs of improvement, the excavated sore was opened up, scraped, curetted, and thoroughly swabbed out with iodised phenol. In spite of this treatment, combined with keeping the wound plugged with peroxide of hydogen, alternating with formalin 1 in 3, together with the antisyphilitic treatment, the phagedænic sore spread with alarming rapidity, and it became evident that a condition of malignancy probably existed: this, despite the fact that no glandular enlargement existed anywhere and the negative microscopic findings. Therefore, heroic measures were considered to be indicated, so, under an anæsthetic, the parts were explored, and the curette, knife, scissors, cautery and nitric acid were freely used in an endeavour to stay the disease, whilst large portions of the tissue that had not sloughed were removed for microscopic examination. Although the infection spread over to the other side, yet the urethra seemed in no way implicated, and lay in the midst of the disease as an isolated tube.

Their pathologist, Dr. Rowlette, reported that the case was one of adeno-carcinoma of the vulva. This diagnosis was only arrived at after he had cut a great many sections.

There were no apparent primary growths in any part of the body, and the only possible original seat of the disease seemed to be in Bartholin's gland.

The CHAIRMAN said he had an opportunity of seeing the case, and leant at first to the idea that it was a form of syphilitic disease. He was particularly struck with the absence of induration of any tissue in the neighbourhood of the disease, which he would have thought likely to be observable in malignancy.

RUPTURED EXTRA-UTERINE PREGNANCY.

Dr. FreeLand exhibited specimens from a case of the above, taken from a patient, æt. 35, who had been married fifteen years, and had had four children and four abortions. She had come to him two weeks before complaining of hæmorrhage, and menstruation overdue two weeks. On examination she was found to have retroverted uterus and a small tubal mass in the left side. He thought she had a tubal pregnancy. She would not remain in hospital; she had considerable pain when she went home. She returned the next day, and the following Tuesday he operated. On opening the abdomen he found the pelvis full of blood. The fœtus had escaped into the abdomen and was attached by the cord to the rest of the ovum in the tube. The ovary was left in position, and she had done very well.

The CHAIRMAN thought it extraordinary that the loss of blood was so inconsiderable, seeing the size of the rent in the tube, unless the rupture took place gradually.

Dr. HOLMES spoke.

DOUBLE PYOSALPINX.

Dr. FitzGibbon exhibited specimens of the above from a patient, at. 31. She had been married seven years, and had one pregnancy, which ended at term, five years before the operation in August last. She had been under observation eighteen months, and during that time very little change was seen in the pelvic condition. The uterus was normal in size, and

hard. On the right side there was a hard mass pressing down on the right fornix, and on the left side they could make out a tube thickened, but not embedded. Her menstrual periods were normal, and she was very little troubled until the last six weeks, when she developed severe pain. The abdomen when opened seemed tolerably normal until he attempted to pull up the intestines, when nothing would move, and he found the whole of Douglas's pouch filled with adherent small intestines. He got the whole of the tumour out without tying any vesels, as they had been obliterated. He closed the stump of the cervix with two interrupted sutures, and packed the pelvis with gauze. Two days after the operation the pulse went up 110, though the temperature neither then nor subsequently went above 99°. He withdrew the gauze and put in a long drainage tube. On the third day the pulse climbed gradually up to 160; the following night it fell to 140. He then put in a shorter tube. She continued to improve; but next morning he found a smell of urine. He replaced the tube with one of rubber, and concluded that the drainage tube had sloughed through the bladder. He kept the tube in although some still came away in the urine. The patient made a good recovery. The case showed the danger of hard drainage tubes put through the abdominal wall into the pelvis, and also showed how pyosalpinx, which was obviously chronic for eighteen months, could still set up an infection of the pelvis, although it was stated that if left for twelve months the pus would become sterile.

Dr. Holmes thought the absence of any menstrual history or pain was a most remarkable thing.

Dr. Jellett thought that the bladder fistula was due to an original extension of the infection to the bladder wall at the place where the two were adherent. Necrotic areas were frequently found, and there was no reason why there should not be one on the bladder muscle that gave way when it lost its support. That would account for the fistula not having formed for several days; obviously it was not made at the operation.

Dr. Gibson said he was sure the pain was sufficiently bad to indicate operation, but they had to consider whether the cure or the disease was the greater evil.

Professor Alfred Smith thought the drainage should have been through the vagina. He did not gather whether the infection was pure or mixed. He thought that streptococci alone became so attenuated in eighteen months as to be harmless.

The CHAIRMAN said he did not think there was any positive knowledge as to when infection became sterile. His own experience was that pyosalpinx might remain quiet for years, and under fresh stimulation might light up again. He was satisfied that where there was reason to believe a swelling to be a pyosalpinx, it was always a possible danger, and should be dealt with in most cases by radical operation. Most of them would be inclined to drain in the direction of the vagina; still it was surprising what effective drainage could be carried on through the aldominal wall.

Dr. FITZGIBBON, in reply, said he started with the intention of draining through the vagina, but from start to finish he did not see the bottom of Douglas's pouch, and he had not the least idea where the ureter was, and at the end of two hours' operation he drained in the easiest direction.

A SHORT CRITICISM OF THE RADICAL CURE OF BACKWARD DISPLACEMENTS OF THE UTERUS.

Dr. Jellett began by discussing the present attitude of gynæcologists towards the radical cure of backward displacements of the uterus. He considered that in all cases in which the patient's symptoms called for relief, a radical operation should be performed in preference to the prolonged use of a persary. As exceptions to this rule he mentioned puerperal displacements, as they could usually be cured by the temporary use of a pessary, and cases in which the circumstances or general health of the patient made operation inadvisable. He showed that, if a patient had to be curetted, the performance of a radical operation prolonged her stay in hospital only by a week. He divided

the different radical operations into three groups:—
(1) Cases in which a major operation has been performed, and in which the peritoneal cavity has been opened. For these cases he always concluded the major operation by performing a ventral suspension. (2) Cases in which the displacement is complicated by adnexal disease. In these cases he advised the opening of the abdomen followed by ventral suspension. Cases of uncomplicated backward displacement. these cases he unhesitatingly advised Alexander's operation on account of its safety and its after-results. He then discussed Alexander's operation, and referred to the statements of Drs. Herman and Galabin, who considered it an essentially dangerous operation. In opposition to this he quoted statistics of 385 cases, practically all of which were successful, and amongst which there was a single death from croupous pneumonia, and unconnected with the operation. His own statistics were as follows:-Forty-four cases were operated on. In 39 the usual double incisions were made, and in 5 a single incision. There were thus 83 separate incisions, and every one of these healed by primary union. One incision subsequently suppurated, owing to the fact that the subcuticular suture broke during removal and was left behind. One patient died, but her death, which was from double croupous pneumonia coming on about a week after the operation, had nothing to say to it In one case the uterus subsequently fell back, and in this case only one ligament had been shortened. The other was left, as it was difficult to find, and as the operation had been already prolonged by the preliminary steps of curetting, trachelorrhaphy, and ligature of piles. In this case the uterus was in a normal position when the patient was seen six months later, but it had fallen back when seen two years later. Two patients at least were subsequently delivered, and after delivery the uterus remained in a normal position. The speaker then stated in detail the reasons he considered Alexander's operation the operation of choice in cases of uncomplicated backward displacement of the uterus.

Professor Alfred Smith said he was against Kelly's operation, as he looked upon the suspension as wrong. He believed in the efficacy of Alexander's operation for simple backward cases. That, however, applied to a limited class of case. If Alexander's operation was used in all cases that came to them, there would not be sufficient beds for them. It was only in the better-class patients that shortening of the round ligaments would come into greatest practice. In a case which he thought an ideal one for radical operation, the uterus righted itself when he removed the pathological conditions. If he had shortened the round ligaments he would have thought that it brought about the result. He considered a modification of Bumm's operation the best.

Dr. Ashe said that even if the round ligaments were shortened they would stretch again. He believed Alexander's operation to be by far the best on physiological grounds. It was surprising how in simple cases complications were found when the abdomen was opened, and that was, he thought, a point in favour of the suspension method. He thought there might be a fear of hernia.

Dr. Holmes said the difficulty was to know when they had not got complications. An enormous number of women who came with backward displacement suffered also from sterility, and no gross lesion was found in the tubes. In 50 per cent. of cases that he had examined, the uterus had gone back after child-birth, and he found cases often get right by inserting a pessary for about two months. He thought there was still room for the pessary in gynæcology, and he did not regard any of the operations as final.

Dr. Gibson said the cases for the Alexander-Adams operation were those in which retroversion occurred after childbirth. He thought the best operation for uncomplicated cases was the Alexander, and out of six which he had examined after childbirth in only one had the uterus gone back.

Dr. FITZGIBBON said that when they were dealing with an uncomplicated case they pre-supposed that the adnexa of the uterus were healthy, and there was nothing to interfere with pregnancy and the proper

involution of the uterus after childbirth. In such cases there was a very large scope for the pessary.

Dr. MATSON said that when he was house surgeon to Mr. Alexander, he had the opportunity of seeing him operate in many cases, and at that time he said he usually placed a pessary in position for about two months after the operation.

Mr. L. G. Gunn said there was a cystoscopic method of examination of the bladder for determining to what extent the uterus had been brought forward. He had found a uterus pulled over somewhat on one side.

The CHAIRMAN recalled a case operated on by Mr. Alexander, in which there were three miscarriages afterwards. If a woman became pregnant after suspension, the peritoneal supports were rent, and there was nothing to prevent recurrence. He assumed that before operation they would see that the uterus was reduced in size. He was certain that there were many cases in which the pessary would give relief, and some in which it would effect a cure.

Dr. JELLETT, in reply, said the difference between the treatment which he advocated and the use of the pessary was a week in hospital, and he thought that was less serious than two or three years' pessary treatment, even if in some cases the pessary succeeded. Kelly's operation was not an ideal one, but it had the advantage of taking very little time to do when the abdomen was already open. So far from Alexander's operation causing a hernia, it would probably cure any inclination to hernia, as the walls of the inguinal canal were sutured and a patulous external ring was closed. Obliquity of the uterus was not, he thought, a matter of importance. In three or four cases in which he only shortened one round ligament, he had in a month or so found the uterus in the middle line. The great majority of cases were those in which the uterus had fallen back after childbirth, and in these there was no necessity to look for causes of sterility, but if there was any doubt as to the condition of the adnexs, he agreed with Dr. Holmes in opening the abdomen. In one of his cases a patient became pregnant afterwards, and had great pain from pulling on the external abdominal ring as the uterus developed. The uterus was also very large, and there was hydramnios. He feared during pregnancy that the operation was in some way responsible for this, but eventually the woman was delivered of a stillborn syphilitic infant. He thought that a similar cause probably accounted for the repeated abortions in the case recorded by Dr. Purefoy.

# CHELSEA CLINICAL SOCIETY.

MEETING HELD JANUARY 19TH, 1909.

The President, Mr A. F. PENNY, F.R.C.S.I., in the Chair.

MR. T. CRISP ENGLISH showed the following cases:—
(1) Laminectomy for paraplegia. A boiler-maker, act. 42, who had had symptoms of pressure upon the fourth dorsal segment for six months. Operation was performed in September, 1907, and a cyst attached to the root of the fourth dorsal nerve inside the membranes was removed. Recovery was rapid and complete. (2) A boy, with considerable enlargement of the spinous process of the sixth cervical vertebra; an excellent skiagram of the whole of the cervical spine by Dr. G. A. Simmons was shown. (3) A case of fracture of the humerus, with musculo-spiral paralysis. Mr. J. HOWELL EVANS presented a further report on

THE CASE OF TUMOUR OF THE JAW
in a girl, æt. 12, which was shown at the last meeting. This little patient was operated upon, an incision to the extent of 6 in. being made parallel, but, for cosmetic reasons, below the lower border of the right jaw, and the soft structures overlying the tumour reflected upwards over the face. An awl was driven through the centre of the base of the tumour, and a Gigli saw passed through the tunnel thus formed. The tumour was sawn off from its base parallel with the outer surface of the jaw without injury either to the sockets of the teeth or mucous membrane of the jaw or cheek. Further pieces were pared off. In consistency the tumour varied from that of bony hardness to the con-

sistency of (softened) fibro-cartilage. A layer of goldleaf was placed over the surface of the jaw. Microscopically the tumour presents the structures of a calcifying cardio-myxo-fibroma. Mr. Howell Evans had not yet come to a definite conclusion as to the origin of this tumour, neither could he give an assured prognosis. He was of opinion, however, that there is not sufficient evidence of malignancy to, at present, warrant resection of the mandible. (Mr. Howell Evans exhibited photographs illustrating the aspect of the patient before and after operation, X-ray photographs of tumour in situ, and tumour removed; also microscopical specimens.)

Dr. ERIC PRITCHARD read a paper on the TREATMENT OF INDIGESTION IN INFANTS, which will be found in another column, under the heading of "Original Papers."

In the discussion that followed,

Dr. WILLIAM EWART dwelt upon the intrinsic value of the paper, which was singularly luminous and lucid. The physiological standpoint adopted by Dr. Eric Pritchard in his clinical conclusions was one which could not lead to disappointment, as the lines which were to be pursued were measured upon those followed with unerring success by Nature. A question might be asked in connection with the principle advanced by Dr. Pritchard that the milk supplied went to the young in each species to educate the stomach to its specialised work in that species, how it was to be explained that milk suited to digestions so different as those of cows and of asses should both be suited for the human infant, whose digestion differed so much from both. With reference to the clinical uses of paraffin, he could entirely endorse the views which had been expressed. He had long administered paraffin in the treatment of enteritis, of colitis, and of constipation, and it entered into the treatment which he had recommended for enteric fever. In the gastrointestinal ailments of infants and of children, he made extensive use of the same remedy.

made extensive use of the same remedy.

Dr. Parkinson thought that more attention should be paid to the food and the manner in which it is given than to the art of administering drugs for the treatment of troubles which should be prevented. Children were often treated as if they were all of one type and made like so many Waterbury watches, instead of which each child was born with different powers of absorption and powers of resistance. Any physician attempting to bring up children on one stereotyped text-book rule was sure to meet with many failures. In his experience he had met with more disease and trouble from over and improper feeding than under-feeding. In a properly trained, healthy child constipation should not exist.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD IN THE FACULTY HALL, FEB. 5TH, 1909.

The President, Dr. WALKER DOWNIE, in the Chair.

DR. JAMES MACLEAN showed a little girl, in good health, who had recently suffered from a most severe and prolonged attack of

CEREBRO-SPINAL MENINGITIS.

He also exhibited the temperature chart, extending over a period of eleven months, to illustrate the extreme rapidity with which the variations occurred. The variations were very often extreme in degree also, sometimes reaching 106°, and getting as low as 98.8°. Dr. Maclean read notes of the case. When the illness began the child was 4 years and 3 months old. Stiffness and pain was complained of in the right hand in the morning. The child was restless during the day, and at 3 p.m. was thought to be dying. Its skin was livid, and petechiæ were present. The temperature was 103°, the pulse very rapid, and the skin so tender that the child could not bear to be touched. The same evening the temperature was 98.8°. Next day the head became retracted, the pupils dilated, and all the other typical symptoms were present. The screaming fits often ended in a kind of trance, when the patient lay passive for a few hours. The feeding was all forced at this time. About the fifth day pain began in the left ear, and two days later in the right

ear and in the eye. After two months there was some improvement in the child's condition. This lasted for over a week, and was followed by an exacerbation of the symptoms. A month later the symptoms were less acute, and the patient in a more passive condition. She had still the catalepsy after the screaming, and required the frequent administration of bromide of potash and antipyrine for that and for twitching squint. This condition lasted for about three months more, when the patient was considered hopeless. She was very emaciated, having been dependent on rectal feeding for nourishment for a long time. Dark hair covered the face and extensor surfaces of the limbs, and the weakness was very extreme. At the end of 61 months of illness there were signs of improvement The left arm began to move; then the right arm. Some two months later the legs could be stretched, and the improvement continued till she could take an interest in dolls and pictures. After in months the patient had recovered from every sign and symptom of the disease, and had no sequelæ, but was very weak. She is now—two months later—quite plump and strong, has no deafness or other defect, and is as alert and intelligent as the average child of her age. The interest in this case turned upon the extreme illness, the duration, and the completeness of the recovery. The feeding was also interesting as showing the large quantities of food that were sometimes taken. In the treatment, anti-meningococcous

serum was tried, but without benefit to the patient.

Mr. HENRY RUTHERFURD showed a girl, æt. 8, who

suffered from

OSSEOUS ANKYLOSIS OF THE JAW which he treated by excision of the condyle and neck of the mandible. The condition followed upon suppurative disease of the middle ear, and an operation for this had been performed on the right ear some time previously. The lower jaw was firmly fixed and could not be moved. After the excision of half an inch of bone a useful movable joint was formed, and the mouth can be widely opened and mastication carried

on with efficiency.

Mr. Henry Rutherfurd also showed two specimens of "Rupture of the Intestine," and read notes of several cases of a like nature. He endeavoured to demonstrate that in these cases the muscular coat of the bowel ruptured as the result of direct injury, and this allowed the mucous coat to become herniated through the opening thus made. After a variable period of time the mucous coat also ruptured, and the contents of the bowel escaped into the peritoneal cavity. Mr. Rutherfurd pointed out the importance of opening the abdomen as soon as possible after an injury, even when there was only symptoms of hæmorrhage, as this allows of any dangerous condition being discovered and attended to before perforation has time to occur.

Dr. KERR LOVE described a case of

PERI-SINUS ABSCESS, with mural thrombus in the sinus, basal meningitis, and tuberculous tumours in the pons, cerebellum, and both sides of the cerebrum. The child had suffered from measles and whooping-cough, and this was followed by symptoms of ear disease. There was tenderness on the right side over the masteid process, and pain behind the ear, with slight bleeding from the ear. An operation was performed. Very little pus was found, and this contained pneumococci and streptococci only. No relief resulting, another operation was performed two days later, and an abscess was found surrounding the sigmoid sinus, but no sinus thrombosis. After a few weeks' treatment the child was fairly well and went home. A month later the wound was septic, and pus was discharging from the meatus. An operation was performed, when the mastoid process and the region of the sinus was filled with granulation tissue. A month later facial paralysis came on without any apparent cause. The tip of the mastoid was removed, but the paralysis got worse. Four days later rigidity of the muscles of the neck set in, and a few days later optic neuritis developed. The temperature rose to 106°, and death ensued.

The post-mortem examination of the head showed that the ear condition was not the primary disease,

but was only an incident in a much more serious condition; and Dr. Kerr Love pointed out the importance of this in tuberculous cases, where the operation for the ear condition may do more harm than good, and

cannot remove the chief seat of the disease.

Dr. Kennedy, who made the post-mortem examination of the head, showed parts of the brain in which many tuberculous masses, about the size of peas, were found. These were situated in the pons, the cerebellum and the cerebral hemispheres. There was a basal meningitis as the result of the tubercles, and this was the cause of death.

Paris, Feb. 14th, 1909.

THREE USEFUL DRUGS.

CAFFEIN, theobromin, and ergotin are three therapeutic agents of great utility as they render signal ervice in complications of various affections.

Caffein exists in green coffee in the proportion of from 3 to 6 per cent. An infusion of coffee is thus very useful in certain cases, but its abuse determines, after prolonged use, agitation, trembling, vertigo, and pal-pitations; there exists, says Prof. Carnot, even a kind of intoxication due to the immoderate use of coffee.

Caffein is also found in tea, cacao, kola, etc.

Being but little soluble in water, salicylate or benzoate of soda has to be added to increase its solubility. Its action and stimulating properties on established, while it is also an excellent diuretic. Consequently it is used as a nervine and muscular tonic in typhoid fever, grippe, fatigue, mental strain, as a cardiac tonic where the heart shows signs of failure, and as a diuretic in a certain number of cases where other agents have been tried without success.

Theobromin is a therapeutic agent of very great value and employed constantly; either before or after

digitalis; it has no cumulative effects.

Theobromin is extracted from cacao, but it has the inconvenience of being insoluble in water, and has to be given in wafers. It can, however, be dissolved in water by the aid of salicylate or acetate of soda.

Theobromin has little or no action on the heart, but on the other hand its diuretic properties are known to Many, however, have failed to derive all the benefit from this drug they had a right to expect, but chiefly because the mode of administration was at fault. Instead of prescribing ten grains three times a day, the wafers should be given every hour for three hours, intense diuresis is generally the result with an important elimination of chlorides. The addition of an equal quantity of phosphate of soda increases its activity.

Theobicmin is particularly prescribed in renal dropsy, heart affections with cedema, and in arterio-

sclerosis.

Ergotin, an excellent hæmostatic, is a vaso-constrictor of the first order affecting especially the small

It acts almost immediately after absorption, and affects principally the muscular coat of the intestine and the uterus.

It is utilised in metrorrhagia due to the presence of phthisis, myocarditis, medullary congestion. In hæmorrhage of the digestive tract it is sometimes beneficial; but in epistaxis and hemoptysis it is un-

AORTIC ANEURYSM. The treatment of aneurysm of the aorta consists chiefly in lacto-vegetarian régime, rest. and the following:

Iodide of potassium, 21 dr. Ext. of opium, 4 gr. Hydrate of chloral, 1 dr.

Water, 10 oz.
One tablespoonful before meals; to be continued until

signs of intolerance set in, when it is dropped, but continued later on.

Injections every week into the gluteal region of a solution of gelatin:

Gelatin, 30 gr. Chloride of sodium, 20 gr. Sterilised water, 7 oz.

One ounce the first week, increasing each week by five drachms until three ounces are reached.

Against oppression, 10 drops of an alcoholic solution of oxy-camphor at 50 per cent. on a piece of sugar

three or four times a day.

To lower the arterial tension, from three to six days daily a solution of trinitrin in a tablespoonful of

Inhalations of nitrite of amyl may be utilised with advantage.

In case of hæmoptysis, a tablespoonful every two hours of

Chloride of calcium, 1 dr. Syrup of opium, 1 oz. Water, 4 oz.

For the cough:

Ext. thébaïque, ½ gr.
Ext. of datura, 1-10 gr.
For one pill; two to three in the 24 hours.

When the aneurysm is of syphilitic origin, one tablespoonful twice a day of:

Biniodide of mercury, 1 gr. Iodide of potassium, 5 dr. Syrup of orange, 14 oz.

Such is the treatment recommended by Prof. Robin for aortic aneurysm.

#### GERMANY.

Berlin, Peb. 14th, 1909.

AT the Medizinische Gesellschaft, Hr. Albu discussed the subject of VISCERAL PTOSIS

as a Constitutional Anomaly. He opposed the view so widely spread that splanchnic ptosis was exclusively a disease of females; it was certainly more frequent with them, but it was not absolutely rare in men; and even in children it was to be observed often enough. The most frequent was nephroptosis. Amongst the material of his Klinik he had met with the condition in 68 per cent, of the women and in 21 per cent, of the men. The most frequent form was nephroptosis, then followed gastro- and entero-ptosis. He had also examined new-born infants, and out of 94 examined had ascertained that ptosis was present in 44 per cent. of the females, and it per cent. of the male infants. He was convinced still further by this circumstance that splanchnic ptosis was not a local affection, resulting, as was so often thought, from relaxation of intraabdominal pressure, but a symptom in part of a con-stitutional anomaly. This found its expression other-wise, as Stiller and Matthes had rightly observed, in the structure of the skeleton and the development of the soft parts. The writers named had described a habitus enteroptoticus, which was in complete agreement with that designated as the habitus phthisicus. As the typical stigma of this growth, which he designated the habitus asthenia universalis he mentioned the roth floating rib, which in the speaker's examinations was by no means always present.

A prominent feature of this habitus was the increased growth as regarded length, which was usually considerably more than the measurement of the extended arms, or of eight times the length of the head. W. A. Freund had pointed out the narrowness of the upper thoracic aperture and the importance of this as regarded the development of phthisis.

In the soft parts were to be found soft, flabby breasts, wide apart in women, general under-nourishment, flaccid abdominal walls with depression of the upper half of the abdomen, combined with fulness of the lower half.

The speaker took the enteroptotic habit for a paralytic one and a disturbance of embryonal development. It was a sign of bodily insufficiency and the result of insufficient care and exercise of the body continued through generations. By means of photo-

graphs and statues he showed that at one time artists preferred to represent men of this habit, and thought from this that at one time it was more general than at present. In the levying of recruits in later years Schwieling had reckoned that an increase of height had taken place during recent years in all the countries inquired into, a fact that was only of value when the other bodily development kept pace with it. That was not the case, however, everywhere. In Prussia fitness for military duty had slightly diminished.

From a therapeutical point of view we were powerless against visceral ptosis, we could at most render the condition latent by bandages, etc. On the other hand, we should strive to develop a healthier and stronger race by appropriate bodily hygiene, gymnastic exercises and so forth.

Hr. Lennhoff was of opinion that a deviation from a so-called normal index, as well as palpability of the kidneys, was no proof of a low bodily condition, other

things had to be taken into consideration as well.

The Deutsch Med. Zeit., February 4th, 1909, contains a communication on the

TREATMENT OF INGROWING TOE-NAIL BY PERCHLORIDE OF IRON.

The method was proposed by Prof. Rehn, and has been in use in the Städ Krankenhaus, Frankfort a/M., for the last fifteen years. It consists in the following: A little lint is wrapped round a bit of stick, and dipped into pure perchloride of iron; it is then dabbed over the inflamed overgrown soft parts, as well as over the ingrowing part of the nail. The applicaas over the ingrowing part of the nail. The applica-tion must be allowed time to sink in and work, so the lint must be kept pressed on the parts for some little time. The process can easily be made quite painless. It should be repeated in 24 hours if required. The iron dries up the parts very quickly, the wall of inflammation shrinks, becomes hard and retracted, the nail brittle, the pain vanishes. In milder cases the parts heal quickly. It is said that even phlegmonous processes disappear. Many of the cases may be treated in the out-patient department.

(No mention is made in the above of a useful little wrinkle, that is—to cut a groove down the length of the nail with a file or fine fret saw. The groove should be fairly deep, but should not, of course, reach the "quick." This makes the nail weak along that line, so that it "gives" there instead of forcing its way into the flesh.—CORR.)

# AUSTRIA.

Vlenna, Peb. 14th, 1909.

SPASMUS PALATINUS.

W. SCHLESINGER presented a man to the meeting of "Innere Medizin," who, after a severe cold a year ago, suffered from a peculiar rushing sound in the head with a strange ticking like a clock. On examining the patient no such sound could be observed by the examiner till the head was half a metre distant. Inspection of the fauces revealed a regular contrac-tion and pause in the muscles of the soft palate causing the uvula and velum to rise upwards and outwards violently, and strike against the side of the orifice.

A case of this nature, free from any other com-plication, he had not met with in the literature on the subject. The remote cause in this case he attributed to hysteria, although he confessed there was

much obscurity in the presumption.

Fuch said this reminded him of a case which he put on record, as remarkable and obscure as Schlesinger's. In his case there was anti-peristalsis of the stomach although no stenosis of the pylorus could be observed by the Röntgen rays. There was also phenomenal movement in the region of the vagus in the same individual.

Beer said he had seen a patient who could cause the same sound at will, in another the tick of a clock could be heard by the movement of the uvula and velum. The latter was the result of a psychical injury where the patient had been saved from drowning. CORRESPONDENCE.

ISOLATED MULTIPLE ARTERIAL DISEASE.

Herman Schlesinger exhibited a male patient, æt. 38, with arterial, probably syphilitic, disease of the carotid, subclavian, and femoral arteries of the left side. All of the tests had Wasserman's positive reaction in an accentuated form.

Wiessel said he understood this to be a central form of stenosis caused by calcification of the medial covering of the artery promoted by the syphilitic

virus.

POLYCYTHÆMIA RUBRA.

This is a disease attributed by many authors to tubercle of the spleen which is probably the true attology of the disease as was shown to be the case in a preparation he exhibited to the members where the spleen was highly tubercular.

The primary virus seems to have been conveyed from a centre in the lungs or genitals where it was originally located. For a year before death the polycythæmia existed in an aggravated form.

Scleroderma.

Stoerk showed a few cases of this disease whose

fundamental change was in the fibrous tissue of the skin, having been induced by sub-acute cellulitis or other inflammatory conditions of the muscles and bones. Having once localised itself the disease assumes many phenomenal forms. It is universally admitted that the fibrous tissue is the local lesion, but the proximate changes are assumed to be of a neuro-

genic character; by others an angio-tropho-neurosis; the latter being the most probable.

Noorden recorded a case of scleroderma where thyreoidin and glycosuria appeared; the former disappearing after medical treatment, but the latter

Stoerk remarked that his case had also glycosuria, which shows a close relationship between this disease and scleroderma. He could not discover any history in his case of thyreoidin, although it may have existed in a minor form.

SERUM AND HÆMORBHAGE.

Wirth gave the members an exhaustive exposition of the serum treatment in eight cases where he was unable to control persistent hæmorrhage by ordinary means, but succeeded with injections of serum obtained from the horse. The respective cases were tonsillotomy effects, nasal hæmorrhage in a case of arterio-sclerosis, hæmoptysis in phthisis, and hæmor-rhage from the bowel. One injection of the serum was usually sufficient to check the hæmorrhage. Where practicable serum was applied locally, such as the nose where a mop of wadding could be inserted after drenching it well with the serum diluted in water. For bleeding from the bowel a clyster of the dilute serum was effectual. In hæmoptysis the best form of administering the serum was by injection, in which it was prompt in four cases, as on the third day no blood could be observed in the sputum. The injections were given subcutaneously in doses of 20 cubic centimetres of the serum taken from the horse. He observed that the serum was much more reliable in this form than the oft used gelatine.

ACROMEGALIA, OSTEOMALACIA, AND STRUMA.

Müller presented a young woman who had all the
symptoms of deep-seated disturbance of the glandular system with internal suppression of the secretions. The prominent external evidence were acromegalia, osteomalacia, and struma. The patient complained of headache, vertigo, angio-neurotic phenomena in the legs, and great reduction in visual acuity. Both kneejoints were so greatly thickened and altered that the patient could only move with difficulty. Both adductors suffered from cramp while the symphysis pubis had the characteristic bill, or pigeon-breast

appearance.

# FROM OUR SPECIAL CORRESPONDENTS AT HOME.

#### SCOTLAND.

EDINBURGH UNIVERSITY.—Among the list of names of prospective recipients of the degree of LL.D. at the forthcoming Spring Graduation Ceremonial are those

of Emeritus Professor Alexander Crum Brown, M.A., of Emeritus Professor Alexander Crum Blown, M.A., M.D., D.Sc., LL.D., F.R.S., and Sir Alfred Keogh, K.C.B., LL.D., Director-General of the Army Medical Service. Professor Kronecker, University of Berne, the Hon. Lord Dundas, and Mr. J. M. Barrie will also receive the same honorary degree at the ceremonial.

GLASGOW UNIVERSITY.—At the last meeting of the University Court the results of the September preliminary examination came under discussion. It seems that of 227 candidates only 28 satisfied the examinersthe percentage of failures was 87 per cent., whereas in Edinburgh, Aberdeen ,and St. Andrew's, on the same papers, the average "plough" was only 59 per cent. The Court appointed a committee to inquire into the matter, and the committee naturally applied to the convener of the Joint Examination Board for permission to scrutinise the rejected papers. The Board, however, declined to allow this, and while admitting the extremely low pass, stated that they saw no reason to question the competency of the Examiner in English, nor to hold a second examination. In the face of this non possumus attitude the Court appear to have been in some difficulty. Probably most impartial persons will agree with Dr. McVail in thinking that many perfectly competent candidates have been rejected, and that the examination was a pedantic redtape examination. It is on the face of it ridiculous that on the same papers 48 per cent, of Edinburgh candidates pass, and in Glasgow only a quarter of the number. Uniformity of examination cannot be attained by uniformity of papers alone; there must be some common ground among the examiners as to the standard of answers desired.

REGISTRATION OF NURSES.—It has for some time been felt that the provisions of the Bill for the Registration of Nurses are unsuitable for the conditions existing in Scotland, and the subject has been under the consideration of an influential committee appointed some time ago by a meeting of physicians, matrons, and hospital superintendents and others directly interested in, or affected by, the proposed system of registration. This committee has just issued a report, in which they suggest a Registration Bill exclusively applicable to Scotland. The present Bill is, they believe, ill-adapted to local needs, but a separate Registration Council in Scotland would stimulate and promote the training of Scottish nurses in a way that a Registration Council sitting in London would not do. It also seems to the committee that all the advantages of a scheme of registration embracing the whole kingdom would be obtained by insisting in any Bill a clause providing that nurses registered in England or in Ireland should also be registered in Scotland. The registration fee of five guineas is regarded as excessive; in the draft

Bill it would not exceed two guineas.

ROYAL MEDICAL SOCIETY'S BANQUET.—The annual dinner of the Society was held in the Society's rooms on February 9th. The Senior President, Dr. Kelman on February 9th. The Senior President, Dr. Reiman McDonald, presided over a gathering of nearly one hundred. The guest of the evening was Principal Sir Donald MacAlister, who proposed the toast of the Royal Medical Society. He spoke of its long existence, extending into three centuries, and of the great names on its roll—Oliver Goldsmith, Darwin, Lister. Going on to speak of medical education, Sir Donald MacAlister said that the Medical Acts had a strictly practical end in view. They bid the General Council see to it that a doctor had the requisite skill and efficiency. A University might impart to, or ask from its graduates more than the minimum; it might insist more "knowledge," but it might not be satisfied with less "skill." Greater proficiency on the one side must not be purchased at the cost of less efficiency on the other. Modern advances in medicine had put new powers into the doctor's hands. But to learn to use them skilfully needed more study in the wards and more practice at the bedside than before. For that more than the second half of the curriculum was required. When the two half sections were more than the whole could contain, something must give. Should it be the first, or the second, half? He commended that as a practical problem worthy of its statesmanship. The solution which was barred was that which would

crush out, or crush up, the second half. The reputation which Edinburgh had won could be kept only by bettering the methods which had in the past enabled them to win their position. The best of teaching would fail if the student had not time to profit by it. Clinical skill could not be crammed. Time and a certain detachment of mind were factors in the product. If these were stinted practical efficiency suffered, and it was by their practical efficiency that doctors must, on the end of the day, stand or fall. It would not become him to forecast, even if he could, the changes that might be needed to secure them against the curtailment or overcrowding of the clinical part of the curriculum. When the need arose, if it had not already arisen, he hoped they would be granted power to institute and to modify the necessary changes. The Medical Council would look after the minimum curriculum; on the super-minimal, after the bare essentials were provided, on the higher instruction and the stricter standard, does the special reputation of a school or university chiefly depend.

#### BELFAST

Queen's University Medical Students' Association.—A meeting of this Association was held on Thursday, February 11th, in the Students' Union, Queen's College, when a paper was read by Dr. H. L. McKisack on "The Medical Student." There was naturally a large attendance of students to hear what one of their most popular clinical teachers had to say upon them. Dr. McKisack's paper was a happy mixture of wit and wisdom. From his position as secretary of the Medical Staff at the Royal Victoria Hospital he was able to point out some of the failings of the student of to-day, but his he did in such a friendly way that none could take offence. The recollections of his own students days in which he indulged also served to show that when he gave good advice as to work, athletics, and so on, he was in the position of the commercial man who said, "Honesty is the best policy; I have tried both." Referring to the frequent complaints of various grievances made by the Association, he came to the conclusion that these grievances, all things considered, were not very serious. He advised every man to have at least one hobby, and commended the latest College movement, the foundation of the Officers' Training Corps. Professor Lindsay congratulated the students on their society, and referred to recent improvements in the College. Professor Symmers, in an amusing speech, referred to Dr. McKisack's advice on various points, and said his would be that they should make bacterioand state the students also spoke, and criticised their teachers. Their principal complaint was that they did not want to be made into anatomists or physiologists—they wanted to be doctors!

#### LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

"THE OPERATION CRAZE."

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—The aseptic and antiseptic ritual having contributed so much towards the safety of patients obliged to submit to operation (some, unfortunately, under the delusion that medical aid or common sense advice can do nothing for them), has now led to the extreme of endeavouring to cure all by a "short cut" and without daring to imply that operation pays the surgeon best, the physician is now almost altogether ignored; and when death occurs soon after any operation the usual convenient diagnosis is made of "heart failure," so commonly noticed in the daily papers! (40 last year at least). Had a physician been consulted in cases where fatal operation was not immediately imperative, and where fatal results accrued, he might have been able to assist the heart and prepare the patient for operation—almost as important, if time permits, as the operation itself!

Every conscientious surgeon must sometimes be reminded of cases in which he was tempted to operate, and which he now regrets, as having, perhaps, unwittingly hastened the patient's demise. How many healthy ovaries have been removed? How many breasts sacrificed from mistaken diagnosis, or, worse again, from mistaken zeal? organs, the loss of which can never be replaced, and by reaction alone on the patients' nerves contribute to the increase of lunacy (at least in neurotic subjects).

Easier to cut a string than unpick a knot, and while admitting the undoubted value of operation in cases where time will not permit of any delay, or in cases where all other treatment has failed, I think I can get some medical men at least to agree with me, that it is time halt was called and operations only undertaken in cases to which the lines in italics applied.

THE NEWSPAPER PRESS AND QUACKERY.

I am, Sir, yours truly,
ALEXANDER DUKE.

London, W.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.
SIR,—In leading articles, and in the correspondence
pages of your paper, the remarkable and deplorable
change of conduct of the Times with regard to quack advertisements has recently been fully exposed and commented upon. The *Times* until lately stood alone among its contemporaries. In its business, no less than in its editorial department, it was in truth the "leading" journal. It sacrificed an income of thousands a year by refusing advertisements of questionable character, readily accepted by every other paper. Now, as you have shown, the *Times* constantly publishes advertisements the character of which is denounced in its editorial columns, and these advertisements may even appear in juxtaposition with the article condemning them. The editorials referred to must really serve as puffs for the quackery; the simple reader naturally believing that no deceptive advertisement can possibly appear in so high-toned a paper. The Daily Telegraph of to-day, Feb. 3rd, follows the example of the Times. It publishes an article headed, "The Drug Habit: An Increasing Evil." The article very ably exposes the evils of the traffic in quack medicines of all kinds. "The prevalence of self-drugging threatens to undermine the moral and physical wellbeing of the community. The habit has been steadily growing for years, and has now assumed such growing for years, and has now assumed such alarming proportions as to have become a matter of grave national importance." In almost the same words that I employed some weeks ago in the MEDICAL PRESS, it first exemplifies these evils by reference to "indigestion" cures, and illustrates them by reference—as I did—to cases of gastric ulcer in which patients often dose themselves until their malady has assumed a mortal phase before seeking medical advice. The article then goes before seeking medical advice. The article then goes on to show the pernicious character of sham tonics containing alcohol, cocaine, etc., employing language practically identical with that which you quoted last week from a similar editorial in the *Times*. For one advertisement of these pernicious compounds that appears in the *Times*, for every one advertisement of a quack medicine which ought not to be accepted by any paper standing in the first rank of journalism, which appears in the Times, a score appear in the Telegraph. The Telegraph, unlike poor provincial papers which plainly state that they "cannot exist" without the income derived from quack advertisements, is making more money than any other newspaper of the day. It has ten or twenty times more advertisements of every class than the *Times*; its editorial expenses of every class than the *limes*; its editorial expenses are perhaps a quarter as great. It is incredible that its noble owner, who has gained his title, his position, from his paper, can be cognisant of the injury that is being inflicted upon the simple, suffering public by all the forms of medical quackery; he cannot be in the least aware of the facts which the article in his own power today demonstrates. Surely the

article in his own paper to-day demonstrates. Surely the motto, noblesse oblige, should apply here. Surely this distinguished nobleman would revolt with disgust from receipt of any income derived from any source

much less tainted than that indicated by his able contributor. It is impossible to believe he is aware of these facts. Is it not possible for you, Sir, to make a personal appeal to him, and to the proprietors of all the leading papers in this matter? Can you not make plain to them, by reference to their own editorial utterances, the extent of the evil they are quite unconsciously abetting? Can you not by some means contrive to reach directly the eyes or ears of the proprietors of our great papers? The movement for a Royal Commission on Quackery now taken in hand by the British Medical Association and the General Medical Council would be brought to a speedy successful issue if supported by papers like the *Telegraph* and *Times*. The case for legislation against quackery is overwhelming; it only needs stating with authority to compel the immediate attention of Parliament. If the great papers would help in this movement they might confer upon the people a benefit as great as any of those which, largely through their efforts, have been those which, largely through the state of th

February 3rd, 1909.

#### THE CENTRAL MIDWIVES BOARD AND

SEPSIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,-In any investigation of the ætiology of puerperal sepsis undertaken in the future, the regulations of the Central Midwives Board must not be over-looked. It is presumably the function of this body to exert itself for the protection of the public against the ministrations of ignorant or careless midwives. It has hitherto performed its duties in such an erratic and irresponsible manner that one hardly feels sur-prised at any of its actions. Nevertheless, all who are interested in obstetric education will be startled at the latest folly of the Board. In a resolution interpretive of one of its regulations, and having the force of a regulation, it is laid down that a midwife during her training must have made "repeated vaginal examinations" of her patients. For the past ten years at least it has been the teaching of all reputable obstetric authorities that in the interests of asepsis, vaginal examinations should, if possible, be avoided altogether. This is the maxim of such writers as Dr. Whitridge Williams, of Johns Hopkins, Dr. Jellett, and Dr. Tweedy, of the Rotunda Hospital, and its justification is found in experience. Yet the Central Midwives Board direct that candidates for registration shall have made "repeated vaginal examinations." vaginal examinations.
I am, Sir, yours truly,
PATHOLOGIST.

#### AUSTRALIA FOR THE SONS OF PROFESSIONAL

#### To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Since my letters dealing with the opportunities offered by Australia to the sons of professional men have appeared in your columns, I have received a large number of communications from doctors, lawyers, chemists, etc., who are anxious to send their sons to Australia and enter them at one of the Agricultural Colleges here or get them straight on to a farm. great has this response been that I have decided to attend the next Annual Meeting of the British Medical Association at Belfast, and seek there an opportunity of bringing the advantages of land settlement in Australia before the members of the Association who may be interested in the subject. I hope to be in London by May, and letters addressed to me at the Royal Colonial Institute, Northumberland Avenue, W.C., will be promptly attended to.

In the meantime, illustrated prospectuses of the various Agricultural Colleges can be obtained by application to Captain Collins, Commonwealth Offices, Victoria Street, S.W., and if any gentlemen decide to send their sons out at once, so as to arrive here in April or May, which is a favourable time of the year for doing so, I should be much obliged if they would notify this to the Secretary of the Immigration League of Australasia, 14, Moore Street, Sydney.

At several of the Colleges in New South Wales, the fees for board and tuition are to be reduced to £10 or £12 per annum, which should bring this invaluable course of agricultural training within the reach of everyone.

I am, Sir, yours truly,
RICHARD ARTHUR, M.D.,
President, Immigration League of Australasia Sydney, December 28th, 1908.

#### THE DUTY ON COCOA.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,-Judging by speeches delivered in various parts SIR,—Judging by speecnes delivered in the duty of the kingdom, our attitude with regard to the duty misunderstood. We have upon cocoa is apparently misunderstood. We have never asked for Protection on cocoa, and for many years no change has taken place in the duty.

The duty on cocoa is raised for revenue and not for Protective purposes. It is in the same category as the duty on tobacco, coffee, wines, etc. The duty differentiates between raw cocoa and manufactured cocoa, that upon raw cocoa being rd. per lb., and that upon manufactured cocoa 2d. per lb. This differthat upon manufactured cocoa ad. per lb. This difference is not primarily designed to give the home manufacturer an advantage, but to place him on an equality with the foreign competitor in the home market. In converting the raw material into manufactured goods there is a large loss resulting from the removal of imperfect beans, dust, outer husks, etc., and loss of weight in roasting. It is to allow for this wastage that the differential duty, as between the raw material and the manufactured product, is imposed. A similar differentiation exists in regard to tobacco, coffee, etc. On cigars double the duty is paid that is paid on unmanufactured tobacco, whilst on raw coffee the duty is 14s. per cwt. against 18s. 8d. per cwt. on roasted coffee. In each case there is a slight advantage to the British manufacturer. In the case of cocoa it amounts to only 2 per cent., or something between one farthing

and one halfpenny per pound.

But even this advantage is counterbalanced by the absence of any rebate or drawback on exported cocoa. On every pound of manufactured cocoa we export we pay 11d. duty, the 1d. representing the difference between a pound of raw cocoa and a pound of manufactured cocoa. By the absence of drawback the home manufacturer is handicapped to the extent of nearly 6 per cent. in comparison with his foreign competitor in neutral markets. In Holland, for example, there is no duty on raw imported cocoa; in France and Germany drawback is allowed on exported cocoa.

The existing duty upon cocoa only illustrates the

difficulty of applying tariffs with absolute justice as between all the interests involved, and we are convinced that the removal of the present duty upon one of the important foods of the people would be a gain to the consumer, and would involve no loss to the manufacturer.

We may add that we have consistently advocated for many years the abolition of the duty on cocoa as on other articles of food.

Yours truly,

CADBURY BROS., LTD.

Birmingham, February 11th, 1909.

[Our readers will understand that we publish the above communication without in any way committing ourselves to any economic point of Tariff Reform, one way or the other. The food question is clearly one of interest to medical men.—ED. M. P. AND C.]

#### **OBITUARY.**

WILLIAM PARSON, M.R.C.S.

WE regret to announce the death, at Godalming, of Dr. William Parson, an ex-mayor of the borough, at the age of 74.

Dr. Parson was medical officer of health at Godalming for 27 years, and was an ex-master of the Apothecaries Company. He was made a magistrate soon after the commission was granted to the borough of Godalming in 1870. He became a member of the

Royal College of Surgeons in 1855, and a licentiate of the Society of Apothecaries in 1856. He was at one time house surgeon to the Hospital for Sick Children, Great Ormond Street.

#### REVIEWS OF BOOKS.

#### DIPHTHERIA IN PRACTICE. (a)

This little manual gives an account of diphtheria based on the experience of the author. It does not pretend to be an exhaustive treatise on the disease, but rather to deal with those points which give rise to difficulties in practice. The author lays great stress on the importance of the clinical as opposed to the bacteriological diagnosis of the disease. In this we are in full agreement with him, but we are also convinced that the ultimate court of appeal, in every case, and not in the so-called doubtful cases only, is the finding of the bacteriologist. Before the days of bacteriology, when observers were at least as compe-tent as they are at present, it used to be taught that the only way to be sure that those patients who had sore throats and recovered from them, had diphtheria was the advent of paralysis. At present we believe that if statistics of treatment are to be of any use in this disease, only those cases in which the diagnosis is verified by bacteriological examination should be included.

Dr. Litchfield is a firm believer in the value of the anti-diphtheritic serum, and advocates doses which appear to us unnecessarily large. The immediate administration of 4,000 units to a patient with mild faucial diphtheria, does not, we believe, give better results than the administration of half that quantity, and is much more likely to be followed by symptoms, which even if they do no harm are unpleasant to the which even it they do no harm are unpleasant to the patient. We confess we do not quite follow our author's meaning when he says "that post-diphtheritic paralysis is not due to a peripheral neuritis. The lesion is a parenchymatous degeneration of the nerves, which is most marked in the peripheral branches." Further, we do not know if he has any histological confermed to support his contention "that the diphtheric evidence to support his contention "that the diphtheria toxin injures the nerves, and that they subsequently degenerate under the stress of function." From a clinical point of view the hypothesis has much to recommend it, but we should have wished also for some histological proof of it. The book is interesting and will repay perusal.

#### A MANUAL OF MIDWIFERY. (b)

THE second edition of this excellent, if somewhat theoretical, work, seems to us to be an advance upon the first, because somewhat more attention has been paid to the practical aspect of obstetrics. Fifty additional pages of reading matter have been added, and they have been exclusively devoted to practical matters, which we are glad to see the author admits were unduly compressed in the first edition. "Thus a good duly compressed in the first edition. "Ihus a good deal of additional space has been devoted to the subjects of Abdominal Palpation, the Puerperium, and Infant Feeding." This is quite right, but there are many other practical subjects which also urgently demand additional space, and we think Dr. Eden would have been well advised if he abandoned part would have been well advised if he abandoned part of the anatomical descriptions with which the book abounds in order to make the necessary space.

Perhaps, however, in a way, Dr. Eden is wise in devoting more space to the subject in which he is an criginal expert, and less to the subject in which he is apparently so hampered by what one must call case-

hardened London teaching; and case-hardened London teaching, though a knowledge of it may be good for the student "who has the fear of the examiner before his eyes," is not good for the advancement of modern obstetrical practice. At the same time we recognise that Dr. Eden has made a distinct effort to break away from the influences of hereditary teaching, and that in many instances he has been signally successful.

The treatment of face and brow presentation, as described by Dr. Eden, is very sketchy. In the case of the former presentation we are told that Herman's method of flexing the head is best. If so, it must be erroneously described, for how pressure on the forehead of an extended head "first raises the presenting part above the brim, and then commences to flex the head" is unintelligible. We are told that morphia should not be given to an eclamptic patient if she is comatose or when chronic nephritis is suspected. Without entering into the merits of the morphia treatment of these cases, we may say that if these limita-tions were universally accepted there would only be a limited scope for the treatment, whereas those who

adopt it do so in practically all cases.

There is no description or apparent mention of publiotomy, although there is a description of vaginal Cæsarean section. We thought it had been settled for quite a long time that the head entered the pelvic brim in a synclitic and not in an asynclitic position, and yet Dr. Eden brings out the old heresy. Fig. 95, which he gives as a reason for thinking there is asynclitism, to our mind shows the head in a synclitic position, are rether would do so if the asynclitic position. position, or, rather, would do so if the pelvis had been shown too. It must be remembered that in a synclitic position of the head the anterior parietal bone lies lowest because the plane of the brim is oblique, but still this is an extended in a synclitic position. oblique, but still this is an anterior parietal presentation.

There are quite a number of plates, and they are good and well reproduced. There is an especially good set of drawings showing the application of forceps, but Dr. Eden as a bacteriologist, as a pathologist, and even as a practical obstetrician, no matter of what school should really recognise that rubber gloves are essentials whose use should be taught by precept and by example. Dr. Eden details on page 219 the conditions under which rubber gloves should be worn, and they are not convincing. We have not come across a drawing in the book in which the operator wears them. The illustrations in the text are numerous; some are original, and many have been borrowed from other sources. As a whole they would be good if either the author or his publishers had not thought it necessary to convert the half-tones of others into ugly line drawings.

In conclusion, we have only to say that, though personally we do not care for Dr. Eden's work, we recognise that it is an excellent exposition of London teaching, and that in its more theoretical portions it is one of great originality and merit.

#### THE SEXUAL QUESTION. (a)

THE author postulates a sexual question pregnant with untold consequences to the happiness and physical well-being of countless millions of as yet un-born, nay, unconceived, human beings. What that question is we are at a loss to discover, although the author defines his object "to harmonise the aspirations of human nature and the data of sociology of the different human races, with the results of natural science and the laws of mental and sexual evolution which these have revealed to us."

Writers on this subject invariably commence by deploring the quasi-ignorance of the young in relation to sexual matters, although, if we look into the matter, we shall find that it is not so much ignorance as lack of instruction. That, at any rate, is a matter that admits of discussion, nay, calls for it though, when it comes to the actual initiation of the young, very

<sup>(</sup>a) "Diphtheria in Practice." By W. F. Litchfield, M.B.Syd, Hon. Assistant Physician, Royal Alexandra Hospital for Children, Sydney. Octavo, pp. 96, with 14 illustrations. London: Bailliere, Tindall and Cox. 1908, Price 3s. 6d. net.
(b) "A Manual of Midwifery." By Thoma Watts Eden, M.D., F.R.C.P., F.R.C.S.E.d., Obstetrical Physician with charge of Outpatients, and Lecturer on Practical Midwifery and Gynecology, Charing Cross Hospital; Physician to Out-patients, queen Charlotte's Lying-in Hospital, &c., &c. Pp. xii, and 555, with 42 plates and 236 illustrations in the text. Second Edition. London: J. and A, Churchill. 1908.

<sup>(</sup>a) "The Sexual Question." By August Forel, M.D., Ph.D., LL.D., formerly Professor of Psychiatry and Director of the Iusane Asylum in Zurich. English adaptation by C. F. Marshall, M.D., F.R.C.S., late Assistant Surgeon to the Hospital for Diseases of the Skin, London. London: Rebman Ltd.

few parents will have the necessary courage, possibly because they themselves require to be first trained.

But supposing we grant the premises and concede that such instruction should be given, does the author suggest that it should take the form of such a work as he has placed in our hands? Are the young, in addition to the practical, working details of sexual intercourse, as given here, to be placed au courant of every individual aberration of the genital instinct, every irregular sexual instinct, from sodomy to sadism, every erotic elucubration of the genitally insane?

It is difficult to resist the conclusion that the education of the young was about the last thing in the writer's mind when he penned this work, which is an enlarged, but not a revised, edition of Acton on the Reproductive Organs. We can quite understand the author's introductory reproach addressed to the French public (of all publics!) they they "are too much afraid of crudities and of calling things by their proper names." It must be conceded that the author does not shrink from the plainest of speaking, and when he has done with a subject there is assuredly very littleft to know. All the same, the mind of the "intelligent, virtuous, educated, and well-brought-up young girl, 21 years of age," whose letter of "grateful thanks" the author embodies in his preface, would be an interesting study, and her conversation would not lack piquancy.

If we could imagine any possible useful purpose to be served by works of this kind we should not shrink from plain-speaking; but, honestly, it appears to us merely to pander to the morbid taste of prurient people. The greater part of it is concerned with practices, a knowledge of which could not be turned to useful account even by a medical man, and to place such information in the hands of the general public is absolutely inexcusable. It is not even nominally addressed to the medical profession, specious though the pretext would have been, and if its publication be allowed to pass unchallenged the law forbidding indecent literature must henceforth rank as a dead letter.

The translator's part is of indifferent quality, abounding in split infinitives and embarrassed phraseology. We are unable to congratulate him either on his choice of a subject or his manner of dealing with it

#### MEDICAL NEWS IN BRIEF.

#### London Fever Hospital.

THE annual general meeting of the Governors of the London Fever Hospital was held on February 12th. Lord Balfour presided. Mr. Norman presented the that only £665 was received in legacies, being £5,000 less than in 1907. Dr. Sidney Phillips, the Senior Physician, read the report, which showed that the total number of patients under treatment during the year was 762, or 90 less than in the previous year, the decrease being due entirely to the lessened number of cases of German measles admitted. Sir Thomas Barlow, in moving the adoption of the report, urged the establishment of voluntary pay hospitals, throughout the country. He would regard it as the greatest possible calamity if the hospitals of the country were all placed under State or municipal administration. The hospital needed help, and he appealed to all who believed in the voluntary system to help it in the good work it was doing. The report was adopted. Lord Balfour said that the institution was doing a great work among that portion of the community which ought not to be allowed to go to public institutions because its members could do something for them. But they could not do everything, and if nothing were done for them in the way in which the institution was doing it they were forced to sponge on the public funds. There were three classes in the

community—those who could not pay anything at all, for whom the community ought to do the best it could, those who could afford to pay for everything necessary for the cure of those dear to them struck down by disease, and a class who could not pay the whole, but could pay part. The London Fever Hospital catered for the last two classes.

#### Needs of Cardiff Infirmary.

At a meeting at the Cardiff Infirmary on February 9th, General Lee presiding, it was said that the treasurer's bank pass-book showed a balance of £16,231 due to the bankers. Payments were authorised for £1,560, thus increasing the overdraft to £17,791, being £6,369 on capital expenditure and £14,422 on working account.

Dr. Tatham Thompson, Chairman of the Medical Board, reported that three applications were received for the post of House-Surgeon, and that Mr. R. V. V. Vaughan had been unanimously appointed and had taken up his duties.

Draft copies of the annual report were presented, and showed that during the year 2,245 in-patients were treated and 16,323 out-patients. The board regretted that a considerable increase in the cost per bed was revealed, but assured the governors that this increase had not resulted from any want of economy in the management of the affairs of the institution. There were various special reasons for the enhanced cost. The income for the year amounted to £12,102, and the expenditure to £15,849. The income had usually fallen short of the expenditure by nearly £3,000. The maintenance of the new wing would involve an additional annual expenditure of £4,000, and it was, therefore, necessary that £7,000 additional income should be assured before the expenditure was balanced by the income, and the board was determined that the new wing should not be opened until this satisfactory result was attained.

#### Notification of Births.

ABOUT a year ago the question of adopting the Notification of Births Act in the city of Aberdeen was before the Public Health Committee of the Town Council, and then, after consideration, it was agreed to receive a deputation from the Aberdeen Medico-Chirurgical Society. The members of the deputation urged certain reasons for delay, and the request for six months' delay was agreed to. More than 12 months have now elapsed, and the matter was brought before a meeting of the Public Health Committee on February 10th, Councillor Kendall Burnett, the convener, presiding. The committee unanimously resolved to recommend the Council to adopt the Act after the lapse of a month, during which any objections to that course of procedure may be considered.

#### The Prince on Tour-

The Prince of Wales paid a private visit on February 12th to the Great Northern Hospital, Holloway, and made a tour of the wards. His Royal Highness also visited the new ward for children, which is to be declared open by the Princes of Wales on the 22nd inst. The Prince inspected the whole of the premises, and expressed himself as being much pleased with everything he saw. He was accompanied by Sir Francis Laking, and was shown round by the assistant matron and the resident medical officer, Dr. Wade.

#### Death During Operation.

AT Westminster, on February 10th, Mr. Troutbeck held an inquest on the body of George Alfred Wisking, aged 29, valet to Lord Claud Hamilton, who died whilst undergoing an operation.

The deceased was suffering from a throat affection, and was ordered an immediate operation. Examination at St. George's Hospital showed that the deceased had a swelling of the face and neck, which prevented him opening his mouth more than half an inch. An abscess under the tongue, apparently caused by some stumps of teeth, had pushed the tongue against the roof of the deceased's mouth. An operation was immediately performed to reduce the swelling, and just as it concluded the deceased stopped breathing.

In the opinion of the surgeon and the anæsthetist, death was due to the swelling of the glottis causing suffocation. This would have occurred if the operation had not been undertaken, but the operation, which was the only chance of saving the man's life, accelerated his death.

The jury returned a verdict in accordance with the medical evidence.

#### Health of London School Children.

INTERESTING facts about the health of London school children are contained in the report on the medical examination of candidates for scholarships made to the County Council Education Committee. Out of a total of 2,848 boys and girls examined last year, no fewer than 1,227 were found to be physically unfit. Very few were absolutely rejected, the great majority being passed, after receiving medical treatment. It is, however, stated that a considerable number of these

were of very poor physique.

Defects of teeth, vision and throat were most common, but several candidates ultimately accepted were found to be suffering from such complaints as heart disease, middle ear disease, high myopia, lateral curvature, and severe anæmia. In the case of junior county scholars, aged from 10 to 12, 1,015 were declared fit, and 790 unfit, and 171 of the latter were referred back for two, and twenty for three defects. Of the 549 candidates for probationer scholarships, awarded to enable pupils to become elementary school teachers, more than half were below the standard, and 74 were suffering from more than one defect. As many as 297 candidates had not been vaccinated.

#### irish Medical Association—Fermanagh Branch.

AT a meeting of the above Association the following resolutions were passed:—Resolved: Though large sums of public money are paid to those who instruct the public in agriculture, dairying, fruit culture, the technicalities of various trades, the care of cattle, fowls, bees, etc., etc., and notwithstanding that the community is taxed for the maintenance of hospitals and sanatoria for the treatment and cure of disease much of which is preventable—no public money has hitherto been available for the remuneration of those properly qualified to instruct the people in matters of hygiene and the preservation of their health. that the Legislature has at length recognised public health lectures as a subject of technical education, and as one entitled to share in the local grants, it is no longer necessary to regard the services of the profession in lecturing and instructing the people as a matter of philanthropy. And while we consider that such philanthropic societies as the Women's National Health Association are deserving of every sympathy and encouragement, we are of opinion that their existence is the strongest possible proof and condemnation of the neglect and incapacity of the Government, central and local, in matters of sanitation and public health. We are further of opinion that medical men should not lecture under the auspices of such philanthropic societies, or at all, unless adequate remunera-tion be provided, and we suggest that these societies should co-operate with the County Councils for the selection and remuneration of suitable lecturers. We desire to point out that if medical men continue to give public health lectures gratuitously philanthropy will be usurping the functions of the Government, and local authorities will never be given the opportunity of exercising their newly-acquired powers of paying for lectures and instruction in hygiene and public health.

#### Compulsory Irish in the New National University.

A MEETING of Dublin students was held last Monday night in order to demonstrate to the public their devotion to the cause of compulsory Irish. The meeting was held in the Round-room of the Mansion House. A resolution was adopted expressing the opinion that no one could be considered educated unless he has received instruction in the language and history of his country, and calling on the Senate of the National University of Ireland to make a knowledge of the Irish language and of Irish history and service of the Irish language and of Irish history and the Irish language and of Iri ledge of the Irish language and of Irish history an essential part of the education of every student at entrance and up to the point at which specialisation begins. Subsequently a torch-light procession was

On the other hand the following petition to the Senate of the National University has been signed by seventy students of the Catholic University School of Medicine:—Gentlemen,—Seeing that a meeting, purporting to represent the opinion of the whole student body of Dublin, has been convened to support the demand for compulsory Irish in the National University, we, the undersigned, representing a considerable number of the students of the Catholic University School of Medicine, Dublin, do hereby wish to dissociate ourselves from that demand, while at the same time we believe that every facility should be afforded for the voluntary study of Irish.

The arguments in favour of our position against coercion have been too fully stated to require reiteration here.

#### The Prince and the College of Surgeons of England.

At the ordinary meeting of the Council, held on February 11th, the President (Mr. Henry Morris) announced that the Prince of Wales had consented to become an Honorary Fellow of the Royal College of Surgeons of England. The votes of the Council were thereupon taken in accordance with the requirements of the charter of the 63rd Vict., and the President declared his Royal Highness to be duly and unani-mously elected an Honorary Fellow of the College. The diploma was presented to his Royal Highness, in the presence of the Council, on Monday, February 15th, when, as has been already announced, the Prince and Princess honoured the College with their presence at the delivery of the Hunterian oration by the President.

#### The Will of Sir Arthur Macan.

SIR ARTHUR VERNON MACAN, M.B., B.A., F.R.C.P.I., of 53 Merrion Square, Dublin, President in 1903 of the Royal College of Physicians in Ireland, and for many years King's Professor in Midwifery in Trinity College, Dublin; an authority on Obstetric Surgery, and President of the Obstetrical Section of the Interand President of the Obstetrical Section of the International Medical Congress, and of the Obstetrical Section of the Royal Academy of Medicine, and of the British Gynæcological Society, who died September 26th last, aged 65 years, eldest son of the Hon. John Macan, Q.C., a former Judge of Bankruptcy in Ireland, left personal estate in the United Kingdom valued at £25,924 19s. 3d. Probate of his will, dated September 24th last, has been granted to his brother, Dr. Jamieson John Macan, M.D., of Crossgates, Cheam, Surrey, and Miss Dorothy Vernon Macan, of ca Merrion Square Dublin, and probate has been 53 Merrion Square, Dublin, and probate has been renounced by Mr. William Edward Peebles. The testator left his mifwifery instruments and objects for the teaching of midwifery to Trinity College, Dublin; his French and German medical books and his English books on midwifery to the Royal College of Physicians, Ireland; his other medical and surgical instruments to Gibbon Fitzgibbon and Arthur Holmes, and the residue of his property to his children—Arthur Vernon, Leila Vernon, Dorothy Vernon, Leslie Fitzgerald, and Eleanor Vernon Osborne.

#### Conjoint Examinations in Ireland.

THE following candidates have passed the final THE following candidates have passed the final examination of the Royal College of Physicians and the Royal College of Surgeons, February, 1909:—
J. J. Barry, C. H. Bryan, F. S. Crean, J. J. Cuskelly, C. J. B. Dunlop, J. J. Dwyer, J. Ellenbogen, D. J. Harty, P. Maguire, J. O'Brien, M. C. O'Hara, D. O'Sullivan, W. G. Ridgway, H. N. Ritchie.

The following candidates have passed the public health examination, February, 1909.—Capt. Wm. O'Sullivan Murphy, I.M.S., M.B., R.U.I., Samuel Poole, M.D., Univ. Edin.

#### The Apothecarles' Hall of Ireland.

THE following candidates having passed the necessary examinations, have been granted the Diploma:—Charles J. Neilan, Thomas Edwin Johnson, and Edmund Smith.

#### NOTICES TO CORRESPONDENTS. &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a Distinctive Signature or Initial, and to avoid the practice of signing themselves "Reader," "Subsoriber," "Old Subsoriber," etc. Much confusion will be spared by attention to this rule.

#### SUBSCRIPTIONS.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

insertion; 6d. per line beyond.

COTTAGE HOSPITAL.—Under the above nom de plume, a correspondent writes as to the best way of drawing up an inexpensive pharmacopæia. It is difficult to answer in a few words, but, speaking generally, a good plan is to restrict the range of prescriptions as far as possible to a few stock mixtures. Tinctures are always expensive, and should be avoided where it can be managed. Liquor strychnies, for instance, is an excellent tonic, better than can in most cases be substituted for the more costly tincture of nux vomics. With a little care and special knowledge, the cost of drugs can often be greatly cut down. A familiar example is the substitution of sulphate of iron for tincture ferri perchlor. Every practical dispenser should be able to supply lots of practical information on this subject.

DR. M. F. D.—The authority is acting entirely within its

DB. M. F. D.—The authority is acting entirely within its rights, and our correspondent admits that he was aware of, and accepted, the conditions at the time of his appointment. To complain and protest, therefore, against the terms of the agreement, at the present time, is not likely to lead to any useful result.

#### THE DOCTOR-ACTOR

ITHE DOUTOR-ACTOR.

It is pleasing to realise that Sir O. Wyndham, from his early training as a doctor, was able in a measure to relieve the pain from which he found his great French confrère, M. Coquelin, suffering when he paid him a visit. Sir Charles, as is generally known, at first followed the medical profession of his father, and as a surgeon he served in the Federal Army during the American Civil War.

Civil War.

DR. E. W. S. O.—Yes, please send on the notes of the case, which appears to be interesting. (2) You had better refer to the Secretary of the local Medical Society. (3) Unless the person in question described himself as a "Surgeon," he cannot be punished. The dentists have obtained a much more pertinent definition of the trespasser—so that any pointed reference to teeth appears to be enough to bring a man within their Act.

SER JURGE (Ristol).—Undoubtedly a natient is entitled to

be enough to bring a man within their Act.

Sub Judice (Bristol).—Undoubtedly a patient is entitled to chose his own consultant, whatever a practitioner's feelings may be in regard to the choice made. But if a patient determines to exercise his own judgment in the matter, against the advice of the practitioner, the latter is naturally absolved of all responsibility of the result. It is always, however, best to acquiesce with the patient's wish, in such cases, irrespective of personal feelings.

## LIQUEUR BRANDY.

INVALUABLE IN THE SICK ROOM, AND IN ALL CASES WHERE A GENUINE MATURED COGNAC IS REQUIRED

Of all Stores, Wine Merchants, &c.

**80/-** per dozen.

Should there be any difficulty in obtaining this Brandy please communicate with the Wholesale Agents, who will send name of nearest dealer.

BROWN, CORE 8 CO., Tower House, 40 Trinity Square. London, E.C.

## Valentine's Meat-Juice

For its ease of absorption and assimilation, its alimentary richness, and where a powerful, concentrated nutrient restorative is indicated, when other foods fail, Valentine's Meat-Juice is recommended by the medical authorities of well known

#### Hospitals, for Consumption.

W. S. Heaton, M. D., Physician to the Home for Consumptives, Philadelphia, Pa. "Valentine's Meat-Juice has been of great service to us in cases where patients were unable to take solid food and refused ordinary beef tea. I can cordially recommend it as the most superior article of the kind."

Dr. Gouel, Physician in Chief Villepinte Hospital for Consumption, Paris, France. "Valentine's Meat-Juice succeeds well in cases of Anaemia and in the treatment of Tuberculosis in an advanced stage, when the stomach is intolerant."

Physicians are invited to send for brochures containing clinical reports.

For sale by European and American Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY, RICHMOND, VIRGINIA, U. S. A. "The Food Par Excellence For a Tired Stomach."

## HOMMEL'S Hæmatogen

CONTAINS NEITHER ALCOHOL NOR ANTISEPTICS

A combination of 80 parts purified and concentrated Hamoglobin with 20 parts chemically pure Glycerine and Aromatic Flavouring.

The best of all the existing preparations of Hæmoglobin. More efficacious than Cod-Liver Oil or the ordinary manufactured preparations of Iron. Very strengthening both for Children and Adults. An energetic Blood Former. Increases the Appetite. Aids Digestion.

- Extremely useful in Rickets, Scrofula, General Debility, Anæmia, Weak Heart, Neurasthenia, and Convalescence from illness such as Pneumonia or Influenza.
- Unsurpassed as a Strengthening Restorative in Diseases of the Lungs. Has a very agreeable taste, and is taken with the utmost relish even by Children.

FREE FROM BACTERIAL GROWTH. UNCHANGED BY KEEPING.

These important qualities are guaranteed by using the highest permissible temperature in the process of manufacture (130° to 140° Fahr. for 24 hours). No guarantee of this description is possible for preparations made by a cold process with ether.

in prescribing, always state "HOMMEL'S" Hæmatogen as spurious imitations are offered.

ONLY SUPPLIED IN FLUID, NOT IN CAPSULES OR OTHER FORMS.

Infants - Take from Half to One Teaspoonful twice a day in milk.

Children - Mdults - One or Two Dessertspoonfuls daily, either pure or mixed with any convenient liquid, One Tablespoonful wice a day before the two principal meals.

SAMPLES AND LITERATURE, gratis and corriage paid, on application.

NICOLAY & CO., 36 & 36a, ST. ANDREW'S HILL, LONDON, E.C.

AGENTS FOR NORTH AMERICA: LEHN & FINK, WILLIAM STREET, NEW YORK.

## PHYTIN

THE NATURAL SALT PHOSPHORUS. IS **OF** PRESENT IN SEEDS AND VEGETABLE TISSUES. NO OTHER DRUG CONTAINS A PERCENTAGE LARGE

## ASSIMILABLE PHOSPHORUS.

Supplied in form of CAPSULES (each containing the Dose—4.2 grains), or in POWDER, or in LIQUID (for Club & Hospital Practice).

Society of Chemical Industry in Basle (Pharm, Dept.), 8 Harp Lane, London, E.C.

ARTHRITISM - DIABETES - ANÆMIA

#### ALEXINE.

(GRANULATED.)

Free Phosphoric Acid-Bi-Phosphate of Manganese-Bi-Phosphate of Iron.

According to the directions and formula of the Joulie Laboratory. ALEXIME realises for the first time the solidification of phosphoric acid by means of a granule containing phosphoric acid accurately measured, chemically pure and entirely free, and bi-phosphate of manganese and bi-phosphate of iron.

SUBSTITUTE FOR GARGLES.

## Formamint

A proved Antiseptic and Prophylactic in diseases of the mouth and throat. Indicated in all cases of septic sore throat such as Tonsillitis, Diphtheria, Scarlet Fever, Measles, Thrush, etc.

From "THE LANCET," Article on Oral Sepsis, Oct. 20th, 1906:—

on vraidepsis, Uci. 2011, 1908;—
"A non-toxic and trustworthy
entiseptic in all ages, differing entirely from simple solutions of formic aldehyde in nature and in action
being much more powerful, devoid
of any irritating properties, and
which on solution by the saliba sets
free that dislatectant in a nascent
form."

"THE PRACTITIONER," Aug., 1907, saps:—

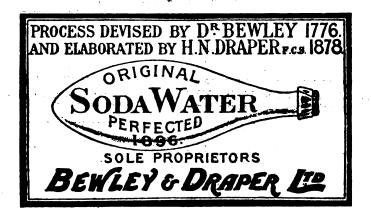

"Generally, the advantages of Formamint are: it is a proved antiseptic and bactericide, it is non-toxic in action, it is more effective than gargles, it is pleasant to take, and, in the form of tablets, it is conveniently portable."

"THE BRITISH MEDICAL JOURNAL," Feb. 22nd, 1908, says:—

"Formamint Tablets are very palatable and without any irritating effect on the throat. . . Their use is recommended in various septic conditions, and as an improvement on gargles as a means of bringing an antiseptic into contact with the fauces."

Literature and Samples Free to the Medical Profession on application to A. WULFING & CO., 12, CHENIES STREET, LONDON, W.C.

X.

This is par excellence the Soda Water for use in the sick-room. It is prescribed by eminent medical men, and has been adopted by the principal Dublin Hospitals. May be obtained in either Syphons or Bottles from all first-class Chemists and Wine Merchants.

Order "Bewley & Draper's Perfected Soda Water."

FOR STRENGTH, PURITY AND NOURISHMENT, THERE IS NOTHING SUPERIOR TO BE FOUND.

-MEDICAL MAG.

IS ADMIRABLY SUITED FOR THE INVALID, BEING SO LIGHT, NOURISHING, STRENGTHENING AND EASY TO DIGEST.

## TAMAR

INDIEN

CRILLON.

#### A Caxative, Refreshing, and Medicated Fruit Coxenge.

VERY AGREEABLE TO TAKE, AND NEVER CAUSING IRRITATION.

Its physiological action assures the immediate relief and . . . effectual cure of . . . . . . . . . .

#### CONSTIPATION.

HÆMORRHOIDS, BILE, HEADACHE, LOSS OF APPETITE, AND INTESTINAL OBSTRUCTIONS.

By augmenting the peristaltic movement of the intestine without producing undue secretion of the liquids. Unlike pills and the usual purgatives, it does not predispose to intestinal sluggishness; and the same dose always produces the same effect—that is to say, never needs increasing.

It is recommended by the most eminent physicians of Paris, notably Drs. BELIN and TARDIEU, who prescribe it constantly for the above complaints, and with the most marked success.

Wholesale—London: E. GRILLON, 67 Southwark Bridge Road, S.E..
Sold by all Chemists and Druggists, 2s. 6d. a box, stamp included.

#### TRADE 'VAPOROLE' BRAND PRODUCTS

for Hypodermic Injection, Inhalation, etc.

The Non-Toxic

## Cyllin

Bactericide

(Medical)

N.B.—It has been found necessary to substitute the term "Rideal-Walker Co-efficient" for that originally introduced by the authors, viz... "Carbolic Acid Co-efficient," owing to the abuse of the latter on the part of unscrupulous manufacturers and vendors.—Vide British Medical Journal, April 6, 1907.

#### Preparations of Cyllin :-

Cyllin Capsules (palatinoids)—Recommended for Gastric or Intestinal Antisepsis.

Cyllin Syrup-For use where indicated in Infantile Diarrhoea.

Cyllin Inhalant—For use with Cyllin Inhalator in suppurative conditions of the bronchial passages, &c.

Lano-Cyllin—For use in Eczema, Pruritus, and other Inflammatory conditions of the Skin.

Cyllin Pastilles—Antiseptic Throat Lozenges; invaluable for purposes of mouth hygiene.

Cyllin Obstetrical Lubricant, Soaps, Lint, Dusting Powder, etc.

See Pamphlet entitled "Standard Chemical Disinfectants." Copies, together with working Samples, sent gratis and postage paid on applying to

Jeyes' Sanitary Compounds Co., Ltd., 64 Cannon Street,

## Influenza?

The present mild outbreak of "influenza," in which gastric and intestinal symptoms are prominent, may be combatted to a large degree by efficient intestinal antisepsis. These symptoms are indisputably those of fermentation, of bacterial origin. It is not necessary that the influenza organism (Pfeiffer's bacillus) should reach the gastric and upper intestinal regions to effect such troubles, as the devitalising influence, produced generally by the growth of this organism in any part of the body, affords free opportunity for the untrammelled activities of certain intestinal organisms which in health remain in a state of inhibition, or at least fail to assume pathogenic powers.

## Cyllin Palatinoids

are accordingly indicated as a direct and reliable preventive measure.

Cyllin Inhalant as an auxiliary agent may be relied upon to supplement the action of Cyllin Palatinoids in the respiratory tubes, more especially the naso-pharynx, pharynx, and upper larynx. To be used pure in special Inhalator.

See Pamphlet entitled "STANDARD CHEMICAL DISINFECTANTS." Copies, together with working Samples, sent gratis and postage paid on applying to

Jeyes' Sanitary Compounds Co., Ltd., 64 Cannon Street, London, E.C.

#### Notes and Comments.

Chemist and

IT may be some consolation for the qualified pharmaceutical chemist to reflect that though the Pharmacy Pharmacist. Act of last session which comes into

force next April, allows trading companies to assume the titles of chemist and druggist, it does not authorise them to call themselves "pharmacists." The bartering away of the title of "chemist" in deference to large business interests, created in a manner by no means creditable to the promoters of joint-stock retail pharmacy businesses, was the most retrograde step taken in medical matters since midwives were recognised as independent practitioners. It is, however, an accomplished fact, and the best must be made of it. The science of pharmacy may flourish in small inde-pendent businesses, but in chemical stores it will find itself ill-mated with the retailing of shoddy silver and plated wares, and such other branches of enterprise as firms of "chemists" throw out to attract customers to their shops. Obviously the business of qualified pharmacists now is to educate the public to recognise the fact that "chemist" does not necessarily mean "chemist" at all, but merely a commercial venture in drugs and anything else that people will buy. As a matter of tactics, we would suggest that duly qualified men should drop the description "chemist" altogether, and describe themselves simply as "pharmacists." In due time people would learn to distinguish between the two, and some of the harm done may be nullified.

" Dill's Diabetic

An inquest was held in Manchester last week to inquire into the death Diabetic of a man named Humby, who, Preparation." having been under medical treatment for diabetes at Nottingham,

and made great improvement, returned recently to Manchester. There he abandoned qualified advice and took to dosing himself with a mixture called "Dill's Diabetic Preparation." sold at 2s. 9d a bottle by one Mooney, a herbalist. Humby did not live long, and the medical man who was called in shortly before his death stated that with proper medical treatment life might have been prolonged for months, if not for years. Mooney declined at the inquest to say what the ingredients of his precious mixture were, but stated that he had cured hundreds of cases, and that he could cure epilepsy and locomotor ataxy as well! The Coroner instructed the jury that if they were satisfied that Humby's life had been materially shortened by the treatment, they could bring in a verdict of manslaughter. However, they merely returned the death as due to diabetes, and the Coroner told Mooney he was lucky that the jury did not connect him with the death. We are glad to

see the Coroner take so firm a stand in a matter of this kind, but cannot understand why he allowed Mooney to refuse to disclose the composition of his stuff. If it had been analysed and found to contain either noxious drugs, or even neutral drugs, it seems to us that it would have had a material bearing upon the view likely to be taken by the jury. What have the local police to say upon the point?

Mr. Bernard Shaw and the Medical

Mr. Bernard Shaw gave a lengthy, interesting, but discursive address to the Medico-Legal Society last week on the "Socialist Criticism of the

Medical Profession." He was, perhaps, hardly in his usual form as a speaker, but there were plenty of sallies and some good stories. Unfortunately, the address was mostly iconoclastic, and as far, at any rate, as the medical part of his audience was concerned, he was preaching to the converted when he detailed the woes of the practitioner and the disabilities under which he suffers. It was somewhat of a surprise to a good many of his hearers that the tone of his remarks was on the whole good-natured, and that he demonstrated more pity than contempt for the unfortunate medical men who struggle to make a decent living in poor neighbourhoods, and, in consequence, his words were well received. Of course, he could not forbear having the usual digs at vaccination, fashionable operations, and other foibles-as he regards themof the profession, but the discoverer of the "nuci-form sac" could not let pass so splendid an opportunity for bearding the lions in their den. One quite legitimate point was made by Mr. Shaw. He dwelt on the poventy of the individual practitioner, and the strain needed to keep up appearances, and from that he proceeded to show the public danger of such a state of things.

In a byegone speech, Mr. Shaw, we believe, once said that the only way to obtain honesty is to provide Prescriptions to obtain nonesty is to provide everybody with £500 a year, and paradoxical as the statement is, it contains the germ of an important truth. There are dangers from riches, but there are greater

dangers to be apprehended from poverty, and if the public wish to obtain pure, disinterested medical advice it must provide itself with a medical profession which can afford to act independently and without regard to consequences. The really extraordinary thing is that in the present welter, they seldom succeed in corrupting medical men, who as a body show an other-worldliness which is astonishing, considering the conditions under which they work. This point, too, was handsomely recognised

by Mr. Shaw. He did not, however, discover to his audience quite how present discontents were to be rectified in any practical form, and that surely is the difficulty of the position. If the profession are to rely on the State, which to the Socialist seems to be the remedy for all ills, we fear that they will only find themselves leaning on a reed which has consistently broken under them every time they put any weight on it, and is likely to break as frequently in the future. The only path of safety seems to be in self-reliance and mutual support, and when those virtues have been shown in dealing with local difficulties, the medical profession has almost always triumphed.

Pioneer Medical Science. THOSE of our readers who can find time for the foreign news—so to speak—of their profession will find much that is of interest in the recently-published report of the Well-

come Research Laboratories. There is no need in the columns of a medical journal to recall the fact that the book relates to the work carried on in connection with the Gordon College, Khartoum. It deals with an immense amount of ethnological, historical, entomological, medical and other matters of general and special scientific interest. A good instance is the observation made by Dr. Franz Werner, of Vienna, with regard to the "spitting habits of certain poisonous snakes." "For a long time," he says, "it has been a matter of discussion as to whether the often-described 'spitting' of the snakes belonging to the genus Naja is a fact or only a traveller's phantasy. Very rarely the habit seems to have been observed in the Indian Naja Tripudians, one of the best-known snakes of our globe; and I do not remember that it has been recorded in connection with other Asiatic species. Such reports as regards African najas are, how-ever, rather frequent, especially from West and South Africa, concerning in Western Africa probably Naja nigricollis, in South Africa the indi-genous Naja flava, or the same species. Had I ever doubted this fact I would have changed my opinion after seeing a full-grown speci-men of Naja nigricollis, the black-necked naja, that had just been brought to me in Gondokoro, spitting directly at my friend and companion, Dr. Sassi, after some chewing movements of the jaws. Fortunately the saliva thus ejected causes no fatal effect when impinging on the unwounded skin; and even the mucous membrane and more delicate parts, such as, more especially, the cornea and conjunctiva of the eye, often reached by the saliva, are, though liable to severe inflammation, in no real danger if the saliva is washed away at once."

The Soudanese the Soudanese medicine-man. The BarberSurgeon. Surgeon to be marked off sharply enough in the persons of the "wise physician,"

the barber-surgeon and the midwife. Some of the traits of these native practitioners, as shown in the following extract, are not altogether unfamiliar in our own experience, albeit there is an immeasurably great gulf fixed between the barber-surgeon and the British general practitioner of the twentieth century. In describing the Dervish medical man, Dr. Zeki says:—"In addition to the 'bassir,' or medicine-man of the Dervishes, there existed the 'hallag,' or barber-surgeon, and the 'daia,' or midwife, a more or less trained woman who attended to obstetric and gynæcological cases. The 'bassir' was considered the wise physician, and was entrusted with the compounding of medicines. Very

often he possessed considerable knowledge, but he took care to secure his fee before prescribing, and too often his cures were a mixture of savage quackery and charlatan tricks. The 'hallag,' who did not possess any special technical knowledge, was nevertheless regarded as a practical workman, and was a familiar figure with his razor, bleeding-horn, and circumcision clamp. It was the fashion to be bled once every six weeks, so that the barbersurgeon was kept busily employed. . . . During convalescence, especially in the case of fractures, the 'bassir' advised the patients to eat dates, said to be the most useful diet for promoting union of bone. In case of delayed union they were wont to assert that failure was due to an insufficient quantity of dates having been eaten."

#### LEADING ARTICLES.

THE MEDICAL ASPECT OF THE REPORT OF THE POOR-LAW COMMISSION.

THE Report of the Poor-law Commission issued last Thursday is, perhaps, the most momentous and important social document issued during the last hundred years, and adequately to consider and to criticise its conclusions would require almost as much space as is occupied by the Majority and Minority Reports, which together cover 500 pages. To do more than summarise in the briefest way its conclusions is all that is possible in the space of an article such as the present, and from our own point of view the medical aspect of the recommendations are the most important. As everybody knows by this time, the guardians are, in the view of the Commission, bodies to be relegated to the limbo of obscurity, and it is no disparagement to many devoted men and women who have worked on such authorities to say that the Commission has come to a conclusion which every social reformer had reached many years ago. Since the days of Oliver Twist the guardians have been synonymous for all that is bête in administration and in civilised life, and they will pass from the stage unmourned, unwept, unhonoured, but not unsung. The spirit which has pervaded the treatment of the poor is, by the Commission's recommendations, to be changed root and branch, and instead of the old exhibition of man's inhumanity to man, we are to have an intelligent differentiation between the deserving poor and the "waster." The first is to be treated as an unfortunate citizen; the latter as a danger to society. Committees of the borough and county councils will be charged with the administration of the service necessary for catering for each class, and while the weak-minded, the epileptic, the unfortunate, and others of similar type will be treated with discriminating tenderness, the incorrigible vagabond will be subjected to discipline which will make him anxious to reform his ways and become a useful member of society. Tempting as it is to dwell on these aspects of this fascinating but complicated subject, we must leave them to consider the more immediately medical problems and the ways in which they are dealt with. Here we mark considerable, perhaps the most considerable, divergence between the majority and minority reports. It is to the credit, rather than otherwise, of the British Medical Association to say that it has "captured" the majority, just as it is to the credit of the Socialists to say that they have succeeded in influencing the minority in the direction they believe to be best. In much that is to be found in the latter division of the report we fancy we trace the hand of an eminent Fabian to whom medical matters are as interesting as the drama. The view of the majority is that the "Public Assistance" Committee of the Councilit is curious that the Commissioners could not originate a description for the new authority, instead of adopting one holus-bolus from the French -should, as regards medical aid, be a kind of King Edward VII. Fund, which should take things as they find them, co-ordinate and level-up institutions for medical relief, and procure a kind of rationale in the methods and ways of hospitals. To this is to be added the duty of organising, or reorganising where it at present exists, a medical service for the poor, where possible, on a provident basis, and, when impossible, the same basis, plus financial assistance from the public funds to meet the case of those unable to pay. What is especially praiseworthy about the scheme, in its latter aspect, is that all practitioners in a locality should be, if they so wish it, available as menibers of the staff of the provident dispensary, and what is, perhaps, a little odd in the case of a State document, is that the British Medical Association is to be the authority to determine the scale of fees and the wage-limit to be applied to members of the dispensary. We can imagine the criticism likely to be applied to such a proposal if made in Parliament by a certain type of "working-man's friend," who lives by vilifying medicine and medical men; but for the British Medical Association itself it is certainly a sign of influence which we will not begrudge it. To our mind, perhaps, the most important point in this part of the document is the recognition of the fact that a citizen must pay the expense of his doctor, and, if unable to do so, the liability lies on the State. At any rate, these proposals are not yet law! The minority report is essentially socialistic in its tendency, and, like all socialistic doctrines, it is admirable in theory, but, alas! extremely difficult to conceive of as practicable this side of the Millennium. The ideal aimed at is the co-ordination of all medical services in one public health service, which shall be primarily preventive in its character, and only incidentally curative. In fact, the curative side is only, it would seem, to apply to those unlucky, or, rather, wrong-headed, individuals who insist on neglecting the admirable precautions designed for them by the preventive service, and so fall into sickness. Our own view emphatically is that the medical officer of health is not the officer to control or be associated with curative medicine. He has his own important and responsible duties, and they are amply sufficient for the energies of the ablest and most energetic of men.

#### CURRENT T PICS.

Medical Inspection of School Children. THE logical nature of the medical inspection of school children is every day becoming more apparent. If the nation is to be physically regenerated on scientific lines, it is obvious that one of the most essential steps will be to detect and, as far as may be, eliminate the defects of the juvenile population. A good illustration of what may be done in this direction may be taken from the recentlyissued report presented by Dr. D. Ll. Williams and Dr. Katherine Drinkwater to the Wrexham Education Committee:—" Up to the end of the year 1,142 children had been examined out of 3,083 on the books. Decayed teeth were found in 761-considerably more than half of the number-and it was regretted that more use was not made of the toothbrush. There were 207 cases of simple enlargement of the tonsils and of overgrowth of the lymphoid tissue in the post-nasal region, known as adenoids. There were 96 children found to be suffering more or less from defective sight, but only 12 from defective hearing; 28 were poorly nourished and under-developed, 75 were suffering from uncleanliness of the head or body, 36 were poorly and inadequately clothed, and in 47 instances the boots were very defective. There were 35 cases of enlarged glands, 35 cases of some form of skin disease, 18 children exhibited some deformity or defect in their constitutions, 29 suffered from heart affections, and 25 from diseases of the lung." regards the treatment of the children. Dr. Williams thinks it would be unwise to trespass on the sphere of the medical practitioner, their cooperation in this work being most essential. It would be quite impossible in regard to the majority of the ailments and defects to persuade or insist upon the parents obtaining proper treatment.

#### The Small-Waisted Woman.

An enterprising lay contemporary, The Tatler, has succeeded in infusing fresh interest into that time-worn subject, tight-lacing. Some time back that journal published a photograph of a famous Parisienne under the sensational title of "the smallest waist in the world." As might have been expected, this challenge was not permitted to pass unanswered, and society has now been enlivened by an article from the same source, asking, "Who has the smallest waist?" Some of the illustrations reveal depths of abysmal foolishness which the small-footed Chinawoman would probably regard with almond-eyed contempt. One lady, "tall and Junoesque," wears a 12-inch metal waist-belt, "an invention of her husband." Happily, few men concern themselves with so criminal a folly; indeed, the majority have no admiration for the tight-laced woman, whose anæmia, indigestion and generally disorganised organic functions render her anything but an attractive being from the male point of view. Another lady is shown in bathing dress, about to take her morning dip in 15-inch corsets. We presume this is the sort of misguided fanatic who would sleep in her "stays," to use the old-fashioned name for this feminine abomination. Another distorted figure is that of a Belgian schoolgirl with a wasp waist, and another older girl who wears a 13-inch corset with ease." Whatever this lady may do during the few elastic years of her youth, it is certain, if she continues to indulge in the practice, she will do so with disease predominant, especially as she elects to throw her whole body out of gear by the use of 41-inch heels! One correspondent of *The Tatler* boasts that her little daughters have worn 15-inch corsets for some time. It would be well, in our opinion, for the lady suffragettes to turn their attention to this matter of small waists, which is of supreme importance to the future position of their sex. Women can hardly hope ever to approach an equality with man while she handicaps herself with the absurdities of feminine dress of the present day, let alone the grotesque fashion of tight-lacing, whereby the natural outlines and natural functions of the body are alike thrown out of balance.

#### The Sale of Poisons.

At a recent prosecution of a London chemist for unlawfully selling prussic acid to a customer without first obtaining his signature in the poison-book, it appeared that the poison was sold by the qualified assistant in charge of the shop to the person in question, who later committed suicide. The sale was noted in the poison-book, though the name of the purchaser was not his real name, and no signature was appended. It appeared that the deceased told the manager of the shop that he wanted the drug to kill his father's dog. For defendant it was urged that a purely technical offence had been committed, and was a matter very different from a wanton infringement of the Act. The Pharmaceutical Society, however, pressed for a conviction, and the magistrate inflicted the maximum penalty of £5, with £25 5s. costs. Laxity of the kind shown in this case demands drastic treatment in the interests of the public. It seems almost incredible that responsible pharmaceutical chemists should run the risks entailed in the neglect of statutory precautions formally and deliberately laid down by Act of Parliament.

#### Parasitic Diseases in Children.

THE crying need of some systematic method of dealing with parasitic diseases in children has long been recognised, and it is not a little curious that in these days of enlightened philanthropy the practical outcome has hitherto been small and ineffectual. All who are acquainted with the facts of out-patient hospital practice in all parts of the kingdom know that many of the children brought thither are affected with ringworm and various forms of pediculosis. The attempt to deal with these complaints in the out-patient department is rarely satisfactory. The cure of ringworm demands patience, care and thoroughness that it is in most cases impossible to procure in the homes of the poor. Under modern methods ringworm has been rendered a much more tractable disease than formerly, but the highly skilled and technical treatment entailed is beyond the resources of the ordinary hospital. School children are brought to the voluntary hospitals to have their ringworm diagnosed and treated, and the school authorities demand unpaid certificates from the honorary medical staff. A more just recognition of the relations of hospitals to public authorities would suggest that if education committees want services of this kind, they should be prepared to pay for them. Then, again, the treatment of pediculosis capitis vel corporis in out-patient departments is far from satisfactory. It is easy enough, as a rule, to destroy the parasites and ovain any given case; it is another and very different matter, however, to avoid the risks of re-infection, because of the absolute hopelessness of securing a proper disinfection of the patient's home environment. On many grounds this question is deserving of close attention on the part of all concerned. Its proper solution can be arrived at only by the intelligent co-operation of voluntary hospitals, education boards and local authorities. A necessary preliminary to that desirable consummation would be an authoritative inquiry into this somewhat complicated problem.

#### The Cancer Mortality.

THE REGISTRAR-GENERAL'S Annual Returns serve an extremely useful purpose by reminding us periodically of the limitations of our knowledge. Although 30,000 die annually of cancer, scientific medicine has hitherto discovered no cause for the malady, nay, more, it cannot be said to have formulated any theory upon the subject that will hold water. An enormous amount of good work has been done, but the results have not been, so far, positive. Many promising lines of research have been opened up, and at any moment, the great discovery may be lighted upon in some bye-path. If it might be permitted to make the remark, the special research organisations, in spite of the fine character of their scientific work, might perhaps gain in breadth were they a little more catholic in their attitude tó outside investigators. Some time ago it was the fashion to scoff at Dr. Doven's bacillus neoformans, but we believe that organism is now recognised by our leading English authorities as invariably associated, in a parasitic sense, with cancer. It is interesting to note that Mr. Samuel Whitchead, in endowing some cancer beds at Middlesex Hospital, in 1792, wrote: "I take the liberty to observe that two principal objects present themselves to my mind on this occasion, namely, the relief of persons suffering under this disease and the investigation of a complaint which, though extremely common, is, both with regard to its natural history and its cure, but imperfectly known." It is interesting to note how imperfect our knowledge on the point still remains after the lapse of 116 years.

#### The Rise of Rhubarb.

The origin of drug taking for remedial purposes is lost in the mists of prehistoric antiquity. Possibly or probably it began at some stage of the world's progress long before that all-important event, the evolution of the genus homo, took place. It is a well-known fact that various lower animals use herbs medicinally; for instance, dogs eat grass. and deer and buffaloes will travel enormous distances to get salt, presumably for therapeutic purposes. So far as man is concerned, it is interesting to learn from the evidence of early Chinese records that rhubarb was an article of commerce 2,700 years before the Christian era. That fact is vouched for by Mr. Harwood Lescher, who recently delivered a learned lecture on the subject. An interesting field of speculation is opened up in this way. It is known that herbivora avoid certain plants by what we usually call "instinct," but is probably the crystallised outcome of prolonged observation. Indeed, it is a matter of surprise that cattle eat yew leaves now and then, and so get poisoned. The wonder here to the man in the street is clearly why a cow has not learnt that yew leaves are deadly. On the whole, it seems not unlikely that the stomachic virtues of rhubarb were known to man at a period compared to which ancient Chinese history is as yesterday.

#### The Radium Institute.

THE announcement a few weeks ago of the foundation of a "Radium Institute" was made with considerable noise, and many of the lay papers hailed the occurrence as the start of a new era in surgery. In this they were only following the lead of a distinguished surgeon, who since his retirement from practice seems to have abandoned much of his erstwhile professional caution. Many medical men are asking themselves what is to be the relation of this much-vaunted institute to medical practice, and Mr. Hall-Edwards, in a letter to a contemporary, sounds a necessary note of warning. It would appear, from the vague statements made, that the Institute is to apply radium to surgical purposes, and to charge suitable fees to those who can afford them. If this is so, then it would appear that an attempt is being made to create a monopoly for the treatment of certain diseases, the monopoly being in the hands of a trust possessed of large funds, and an amount of patronage which makes it all-powerful. If this be really what the Institute is, it is the duty of the profession to speak out clearly its disapproval of the scheme. An enterprise of this kind should be in the form of a medical charity for the benefit of persons of small means. To use funds given for charitable endowment for the purpose of making money in fees is to alienate the purpose of the endowment, and to add yet another to the many forms of competition which medical men, consultant and otherwise, are called upon to face. The straits into which the medical profession have been driven are to a large extent attributable to the unthinking kindness of goodnatured folk who pour money like water into the coffers of the medical charities, but take no heed of the way in which it is spent. While appreciating to the utmost the conspicuous humanity that has prompted the foundation of the Radium Institute, we trust that sufficient wisdom will be instilled into its counsels to enable it to steer clear of injury to the interests of medical practitioners. Why should not representatives of all branches of the medical profession, consultant and otherwise, sit on the executive of the Institute?

#### PERSONAL.

THE PRINCE AND PRINCESS OF WALES, accompanied by Sir Frederick Treves, paid a visit to the London Hospital on Saturday afternoon last. Their Royal Highnesses visited the out-patients' department and the new hot-air bath, and inspected the drug department and the various wards. They also entered the medical college, and witnessed a number of experiments by the professors.

PRINCESS VICTORIA OF SCHLESWIG-HOLSTEIN opened the new wards for children at the Royal Portsmouth Hospital, on February 3rd. The Princess declared the wards open, naming them "The Edward and Mary," after Prince Edward and Princess Mary of Wales, and

"The Young Ward," after the Chairman of the Building Committee. The hospital was then inspected, and after taking tea in the upper new ward the Princess left for Admiralty House.

THE University of Edinburgh have offered the honorary LL.D. degree to Sir Alfred Keogh, K.C.B., Director-General of the Army Medical Corps.

PROFESSOR DIEUDONNE, who went to India in 1897 to investigate the plague epidemic as a member of Professor Koch's Commission, has been appointed "Referent" for the kingdom of Bavaria in succession to Dr. von Grashey, who is retiring.

Mr. S. A. Ballantyne, M.B., Ch.B.Ed., F.R.C.S. Ed., has been appointed Honorary Surgeon to the Coventry and Warwickshire Hospital.

LAST week a handsome presentation was made to Dr. Midwinter, of Anerley, of a testimonial upon the conclusion of a long practice in this district.

Dr. L. NICHOLLS, of the Colonial Civil Service, has been appointed District Medical Officer, Bacteriologist, and Lecturer on Sanitation in St. Lucia, West Indies.

The trustees of the bequest of the late Mr. James Dick have allocated more than £311,000 to charities in different parts of Scotland. The Victoria and the Western Infirmaries at Glasgow receive £30,000 each.

THE University of Cambridge have appointed Dr. W. H. R. Rivers, University Lecturer in Experimental Psychology, to represent the University at the celevation in July next of the fiftieth anniversary of the foundation of the Anthropological Society of Paris.

The late Mr. J. A. D. Shipley, of Newcastle, left the residue of his estate, which, after paying various bequests, is estimated at about £100,000, for division among various local charities, including the Royal Victoria Infirmary and other medical charities.

THE annual general Court of Governors of the Charing Cross Hospital was held in the board-room on February 18th, under the chairmanship of the Earl of Kilmorey, K.P., who is retiring from that position in March, when he will be succeeded by Viscount Ridley.

DR. F. W. HEWITT, M.V.O., who holds the position of Anæsthetist to His Majesty the King, gave evidence on February 10th before the committee which is now sitting, under the chairmanship of Sir Mackenzie Chalmers, K.C.B., to inquire into the law relating to coroners and coroners' inquests.

PROFESSOR CHARLES, M.D., F.R.U.I., D.Sc., F.R.S.E., late Professor of Anatomy and Physiology in the Royal University of Ireland, has lately presented a gold medal to be annually competed for by the anatomy and physiology classes alternately in memory of his eldest son, Captain G. E. Charles, I.M.S., whose early death cut short a most brilliant career.

WE regret to learn of the resignation by Mr. Alban H. G. Doran, F.R.C.S., of his position as Senior Surgeon to the Samaritan (Free) Hospital for Women, Marylebone Road. In recognition of his services to the hospital, the Committee of Management have decided to hold a complimentary dinner at the Imperial Restaurant on March 9th.

SPECIAL terms for travelling expenses and hotel accommodation for those who wish to attend the International Congress of Ophthalmology, which will be held at Naples from March 2nd to April 7th, are being arranged. Anyone wishing to attend should make early application to one of the corresponding members for this country: Mr. Walter H. Jessop, 73 Harley Street, London, W.; Dr. George Mackay, 20 Drumsheugh Gardens, Edinburgh; and Sir Henry Swanzy, 23 Merrion Square, Dublin.

#### A CLINICAL LECTURE

CN

#### UNCOMMON TYPES OF COMMON DISEASES.

By JAMES ALEXANDER LINDSAY, M.D., F.R.C.P.Lond.,

Professor of Medicine, Queen's University, Belfast.

When face to face with a difficult problem in diagnosis we shall do well to remind ourselves that we are much more likely to be dealing with an uncommon type of a common disease than with a rare disease—properly so-called. Rare diseases are rare—let us hold fast to that obvious, but not unfruitful, truism. Uncommon types of common diseases are not rare, and are a fruitful source of difficulty and error in diagnosis. We are all too apt to regard diseases as well-defined and distinct entities (an error which the clear-cut descriptions of text-books do much to perpetuate), instead of being the every varying response of very different organisms to some disturbing influence, whether toxic or otherwise. We are accustomed to the maxim, a true one in the main, "we must treat the patient and not the disease." We are less accustomed to the habit of mind of studying the diseased individual rather than the disease. We must avoid making an abstraction of a condition of which we know nothing apart from its manifestations in the individual.

Instead of being a matter of surprise that disease should vary within wide limits, it is, in fact, just what we might expect. Age, sex, habits, heredity, race, previous diseases, social militum, diet, and other conditions modify, often to an essential extent, the response of the organism to disease. We have many books upon "Children's Diseases," but, as a matter of fact, the diseases absolutely limited to childhood are few in number. What the writers are really concerned with is "Disease in Children." Age may be the most potent element in prognosis—as in pneumonia. A faulty, nervous heredity may impart a grave significance to apparently trifling sources of irritation. The dose and virulence of a toxin, the state of health of the individual at the time of infection, the promptitude or slackness with which the early manifestations are dealt with—these, and many other factors which need not be considered in detail, explain why disease presents an ever-varying picture, so variable, indeed, that only an extended experience and an open mind can preserve us from serious error. Our conceptions of disease must not become stereotyped or fossilised.

I propose to take a few of the common diseases and briefly advert to some of the more striking departures from types which have come under my own personal observation. Some of these, no doubt, will be familiar to many, if not most of my readers. Let us take the following conditions, and the list might be easily extended:—

Pneumonia, Typhoid fever, Scarlatina, Pulmonary phthisis, Aneurysm, Gastric ulcer, Pernicious anæmia, Cerebral tumour.

#### 1.—PNEUMONIA.

Pneumonia is the type of a sthenic disease, of an acute infection, and probably no disease is, on the whole, more uniform in its manifestations. The sudden onset, the initial rigor, the marked dyspnæa, the altered pulse-respiration rate, the characteristic sputum, the peculiar pyrexial curve, the obvious physical signs in the lungs these are highly significant and, on the whole, remarkably constant. Yet striking exceptions occur. I have seen several cases of pneumonia where the temperature remained normal throughout, or only rose slightly a few hours before death. I

have seen a case, an elderly patient, where death took place within twelve hours of the initial rigor. In another case, a child of 7, the crisis did not occur until the 20th day the delay being apparently due to successive invasions of fresh lung tissue, the secondary attacks overlapping the primary one. I have seen a good many cases where the onset was spread over three or four days, the early symptoms being vague, and the early physical signs being either quite vague or simply a small patch of limited crepitus at one base. These cases are commonly put down as "influenza fol-lowed by pneumonia," but there can be little doubt that many of them are pneumonic from the outset. Cases of pneumonia ephemeris are often misinterpreted. In this condition the attack sets in with characteristic symptoms and signs, but comes to an abrupt termination in two or three days, the verdict often being "only a severe cold." But a severe cold does not involve a very sudden seizure, marked physical prostration, and perhaps a spit or two of red material—features which may often be detected in pneumonia ephemeris. I need hardly say that pneumonia sometimes sets in with a clinical syndrome resembling that of meningitis-intinical syndrome resembling that of meningits—intense headache, convulsions, coma—which is one of the well-known pitfalls of the unwary practitioner. A glance at the alæ nasi, and an adequate examination of the chest will keep us right in this matter. The latency of the physical signs in the early days of pneumonia is a well-known source of difficulty. I have known a case where with typical onset and characteristic symptoms nothing could be discovered in the chest until the fourth day.

#### 2.—TYPHOID FEVER.

Unlike pneumonia, typhoid fever is a protean disease—its manifestations are highly variable. There is hardly a symptom in the clinical syndrome which is not occasionally absent. I have not chanced to see a non-pyiexial case, but such cases are recorded. I have seen a case with a sharp sthenic onset, leading to apprehensions of typhus. I have seen a well-marked meningeal onset in a child, which presented the features of retraction of the head, squint and coma, but the character of the stools and the course of the case soon made the diagnosis clear. I have seen a case where, by successive relapses, without any obvious complication, the pyrexial period was prolonged into the twelfth week, the patient ultimately making an excellent recevery. I have known the initial severe frontal head ache—a symptom of considerable diagnostic value—to be entirely absent. I have known the bowels to act normally throughout the attack. I have known the tongue to remain clean until the disease was well developed. I have known a patient to die suddenly from profuse intestinal hæmorrhage, in whom, a few hours before death, the abdomen was slack, free from distension, pain, or tenderness, and where the pulse was good. Such cases are a wholesome reminder of the need for caution in prognosis in typhoid fever. Some cases which have been diagnosed "typhoid fever. Some cases which have been diagnosed "typhoid fever. Some cases which have been diagnosed "typhoid fever. Some cases which have been diagnosed the outset, and the distinction is often difficult and may be even impossible. The practitioner may get a hint by watching the tongue—uniformly furred in tuberculosis, red at the tin and edges in typhoid; by attention to the skin—almost always moist in tuberculosis, variable and sometimes dry in typhoid; by noting the pulse—more frequent in tuberculosis in proportion to the temperature, dicrotic in typhoid; by watching the

temperature, the abdomen, the lungs, and by Widal's reaction. This reaction is found in about 90 per cent. of cases of typhoid. It is occasionally found in other conditions, such as typhus fever and cerebro-spinal meningitis. The reaction is, therefore, not specific.

#### 3.—SCARLATINA.

The diagnosis of mild and uncharacteristic cases of scarlatina is one of the most difficult tasks in medical practice, and, with the utmost care and circumspection, we must expect to be occasionally deceived. The disease has no constant features. Highly characteristic in a typical case as are the conditions of skin, throat, tongue, pulse, temperature, etc., these may all fail us or leave us in doubt. I remember a case which occurred in my practice many years ago. I was called to see a little girl who was covered from head to throat with a profuse scarlet rash. But the temperature was normal, the pulse not accelerated, the tongue clean, and the little patient was playing with her toys, calling out for food, and wondering why she was being kept in bed and on a milk diet. I expressed the opinion that the case was probably not scarlatina. I was mistaken, however, as the further development of the case clearly proved.

In most cases of even very mild scarlatina we get a hint, if we have the intelligence to take it. The onset is nearly always more abrupt than would be probable in any alternative view of the case. The child very often vomits once or twice, even in slight cases. The pulse nearly always shows marked acceleration—a point upon which a good deal of reliance may be placed. Faucial symptoms occur early, are very seldom entirely absent, but may be very slight, and the patient may not complain of them at all.

#### 4.—PULMONARY PHTHISIS.

A whole lecture might easily be devoted to the variations in pulmonary phthisis and the diagnostic pitfalls which have to be avoided. The sputum should, of course, always be examined when it can be obtained. The presence of tubercle bacilli is decisive, that of elastic tissue hardly less so. In many cases, however, there is no sputum, or it cannot be obtained.

A robust physique and a well-developed thorax are no certain protection against tubercular infection. I have met the disease not infrequently in persons who might have been thought à priori to be most unlikely subjects of invasion. Further, the disease may find a lodgment, and even make considerable progress, without either pyrexia or loss of flesh. This statement may be challenged, but the evidence on the subject is really decisive. The thermometer and the weighing machine are of inestimable value in doubtful cases, but the information which they afford is not in all cases conclusive. In medicine, we must not reason from negatives. In the present case it is not safe to say to a patient—"You are not feverish, and you have not lost weight; therefore you have not got phthisis."

The physical signs of commencing phthisis are in not a few cases equivocal. We look for, and we generally find, some localisation of signs at one apex, some impairment of expansion, some muffling of percussion resonance, some harshness or feebleness of breath sounds, some increase of vocal fremitus and vocal resonance. But the condition may be quite different from the above familiar clinical picture. The signs may be those of pleurisy, or bronchitis, or pneumonia, while tuberculosis is really the primary fact. The fact that pleurisy is often tubercular, or a precursor of pulmonary phthisis, is now well known, and the more we study the subject the closer will this connection appear to be, but we must not adopt the extreme view that all pleurisies are tubercular. Pleurisy can be excited by many micro-organisms and the rôle of the pneumococcus is possibly hardly less influential than that of the tubercle bacillus. It is less generally recognised that pulmonary phthisis may set in with physical signs not immediately distinguishable from those of bronchitis, but of this fact I have had conclusive evidence in my practice. No doubt, the resemblance of the conditions is only temporary. Before many days or weeks have passed the bronchitic rales become metallic or crepitant, they tend to become more or less localised, the breathing and the percussion note undergo significant changes. Pneumonic phthisis may closely simulate pneumonia, the physical signs of the two conditions being for a time identical, but error may be escaped by attention to the mode of onset, the course of the temperature, and the characters of the sputum.

A chronic fibroid tuberculosis of one upper lobe, with emphysema of the adjacent portions of lung, may produce a clinical syndrome closely resembling that of asthma, and error is all the more likely inasmuch as the association of asthma and tuberculosis is a rare one. The following clinical rule will be found useful:—In a case clinically resembling asthma, where the patient is young, below normal weight and of poor physique, consider the possibility of fibroid tuberculosis, examine the apices with special care, inquire into history, especially the occurrence of hæmoptysis; examine the sputum.

5.—ANEURYSM.

The clinical picture of fully-developed thoracic aneurysm is usually characteristic, and diagnosis is obvious, but the difficulties of diagnosis at an early stage of the disease are often great. The patient may complain only of a vague feeling of oppression or discomfort in the chest, and physical examination may be negative; or a teasing cough, an unexplained hæmoptysis, a persistent hoarseness, or a quasi-asthmatic seizure may be the first symptom. Many of these cases are misinterpreted and subjected to a futile course of treatment, directed to a supposed lesion of the larynx or lungs. If we carefully keep before our minds in such cases the possibility of aneurysm, our difficulties will be lightened and a more or less probable diagnosis may be made. The subject of thoracic aneurysm is in most cases a male at or about middle life, in the great majority of cases there is a history of syphilis, the general state of nutrition is often good, there is frequently evidence of premature vascular degeneration, careful percussion of the upper part of the thorax will often reveal an area of dulness, the pupils may be unequal, tracheal tugging may be recognised, and so on. It is probable that once on the track of an aneurysm we may be able to discover it.

The danger is that we may be wholly misled by uncharacteristic symptoms. It is a good clinical rule-In the presence of obscure thoracic symptoms do not forget to weigh carefully the possibility of aneurysm.'

#### 6.—GASTRIC ULCER.

In the presence of a painful dyspepsia the possibility of gastric ulcer will always naturally come in for consideration. In a large proportion of cases we find the following syndrome: Pain of a somewhat intense character, located in the epigastric or submammary regions, or in the back, coming on twenty minutes or half-an-hour or more after food, much affected by the character of the diet, relieved by vomiting; a small area of well-defined tenderness in the epigastrium; occasional vomiting, with or without blood; a condition of hyper-acidity of the gastric contents. Age, sex, and the presence of anæmia may assist the diagnosis. Hæmatemesis is often decisive, but we must bear in mind Hale White's teaching that a good many of these cases are gastrostaxis, and not ulcer. What is even more important is the fact that hæmorrhage is often absent in cases of undoubted ulcer—perhaps in nearly half the total number.

Difficulties of diagnosis may arise as follows:—The pain may be uncharacteristic. It may be relieved by taking food, though I believe this to be very rare in gastric ulcer, while it is the rule in duodenal ulcer. There may be no vomiting and no hæmatemesis. The patient may be a young and obviously neurotic female, and the difficulty of excluding gastralgia may be considerable. I suggest the following rules: Severe persistent gastric pain in a young woman is far more likely to be due to ulcer than to gastralgia. This latter condition is somewhat rare. The pain of ulcer is more constant day by day, more consistent, more closely related to the ingestion of food, more definitely relieved by vomiting. The area of epigastric tenderness is rarely absent in ulcer. It requires deep pressure to bring it out, while in gastralgia the hyperæsthesia

seems to be superficial, and pain is caused even by a light touch. The hyperacidity of the gastric contents in ulcer is almost constant. In gastralgia the patient sometimes complains of as much pain after a few mouthfuls of water as after a beefsteak. This never occurs in ulcer.

Painful dyspepsia, due, not to neurosis, but to flatulent dyspepsia or hyperacidity, is usually easily recognised, and can be readily controlled by regulation of the diet and appropriate medicines. Its comparative amenability to treatment—dietetic and medicinal—helps to distinguish it from ulcer and gastralgia.

7.—PERNICIOUS ANÆMIA.

That, after excluding all cases of profound anæmia due to hæmorrhage, malignant disease, pregnancy, intestinal parasites, renal disease, and some other conditions, there remains a group of cases to which the term of essential or pernicious anæmia may be fairly applied, is the opinion of the majority of clinical observers; but the subject is still involved in great obscurity. That pernicious anæmia can be distinguished from profound secondary anæmias by the blood examination alone is a most doubtful proposition. Most observers have seen cases where the blood presented the "pernicious type," but where the subsequent development of the case provd that some one of the above enumerated causes of severe anæmia was the true explanation. Malignant disease is the most frequent source of error. Two cases stand out in my recollection where the blood examination favoured the diagnosis of pernicious anæmia. One died a few years later of uræmic coma; the other was found at the autopsy to be the subject of malignant disease of the small intestine. It is well to accept pernicious anæmia as a provisional, rather than a substantive, diagnosis, to search carefully for a primary cause for the anæmia, and to bear in mind that only time and a careful diagnosis by exclusion justify the acceptance of pernicious anæmia as a final diagnosis. It seems probable that pernicious anæmia, understood in this restricted sense, is not a distinct entity with a definite causation and pathology, but rather the late result of various causes of profound hæmolysis, just as "arthritis deformans" is probably not a definite pathological entity, but a late and profound disorganisation of joints depending on the operation of several toxins

8.—CEREBRAL TUMOUR. Every student knows the classical signs of cerebral tumour—headache, vomiting, double optic neuritis, convulsive seizure. If every case presented these signs in typical form and in combination, the labour of diagnosis would be, indeed, light. Unhappily, untypical cases are common—perhaps nearly as common as typical cases. In a recent case in my own experience almost the only complaint of the patient was of loss of vision in one eye; yet the autopsv revealed the presence of a large cerebral tumour. In other cases vague and persistent headache, not always severe, is almost the only symptom, until some day a convulsion suggests the real root of the mischief. In yet another type of case the patient undergoes a process of mental and moral deterioration. He becomes neglectful of his work, his memory is impaired, and he becomes morose or irritable. Our suspicions may turn in the direction of general paralysis of the insane or some other form of dementia, while the real mischief is a cerebral tumour.

I might easily give further instances of "Uncommon Types of Common Diseases." It would not be difficult to illustrate further the protean character of disease. Nature does not proceed on hard and fast lines. There are few of her laws which have not got their exception. It has been well said that there are two words which have no place in medicine—viz., "Always" and "Never." The moral for us is to keep out conceptions of disease flexible and fluid. to guard against hard-and-fast rules and stereotyped ideas, to be careful not to argue much from negatives, to be vigilant in diagnosis, and to be always ready to reconsider our views in the light of fresh evidence.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Felix Mendel, M.D., Beenn (Ruhr.). Subject: "The Present Position of Intravenous Treatment."

#### ORIGINAL PAPERS.

A SHORT CRITICISM OF

#### RADICAL OPERATIONS FOR THE CURE OF BACKWARD DISPLACE-MENTS OF THE UTERUS. (a)

By HENRY JELLETT, M.D., F.R.C.P.I.,

Gynmocologist and Obstetric Physician to Dr. Steeven's Hospital.

Dublin.

EVER since the first systematic practice of gynæcology began the non-gynæcological mind, both lay and medical, has considered a gynæcologist as a person whose principal duty it is to insert pessaries, and who does so on every available occasion. It is probable that in the past there has been some justification for this belief, because there were but few alternative measures which could be adopted with safety for the relief of one of the most frequent class of female ailments, namely, uterine displacements. Gynæcological practices have, however, widely changed during the past ten years, and though it is not possible to banish at present the pessary, the majority of gynæcologists no longer regard it as affording the best method of treating uterine displacements, but rather as an ancillary method which one may be forced to use by the special circumstances of the case. This change has come about with comparative rapidity. When I was assistant at the Rotunda between ten and thirteen years ago, I think I am right in saying that the general practice was only to perform radical operation for the cure of backward displacements in exceptional cases. In such cases the operation was usually performed by the vagina, and took the form of Mackenradt's or Dührssen's vaginal fixation of the uterus. These operations, however, came to be regarded as likely to be dangerous during pregnancy and labour, and consequently their use was limited to cases in which the patient had passed the childbearing period.

Five years ago one's views on radical operations had advanced a stage, and many gynæcologists considered that such operations should be performed if there was any difficulty either in fitting a suitable pessary or in having it looked after subsequently. My own practice in hospital was that, if a patient who lived in Dublin came to me with a backward displacement, I put in a pessary, but if she came from the country, or was a soldier's wife and likely to leave Dublin. I did a radical operation. Most operators, I think, preferred in such cases Howard Kelly's operation of ventral suspension of the uterus.

From this stage it is only a short step to the views which are held by some operators at present, and with which I personally agree, namely, that if a woman is suffering from a displacement which requires relief, a radical operation should always be performed in preference to inserting a pessary, unless there are any special circumstances which make operations of any kind inadvisable. My own practice is this:—If a patient has to be curetted, or to have any other minor gynæcological operation performed, and if she has a backward displacement of the uterus I always operate on the displacement at the same time. The same rule applies even more strongly in the case of major gynæcological operations, with the exception of hysterectomy. In these cases, however, the radical cure of a backward displacement can hardly be regarded as a distinct operation, seeing that it consists merely in inserting the peritoneal sutures in a particular way.

There are, of course, exceptions to this rule. I have mentioned above one group of exceptions, namely, when operative procedures are contra-indicated by the condition of the patient. The only other exception which occurs to me at the moment is in cases of puerperal or nost-puerperal displacements, as they can usually be cured by a very temporary use of a pessary. I do not think that it is necessary for me to dwell

(a) Paper read before the Obstetrical Section of the Royal Academy of Medicine in Ireland, on January 29th, 1909. further trouble.

at any great length on the reasons for adopting this practice. No one, I think, will deny that, provided operative procedures are safe and give a good afterresult, they are preferable to the prolonged wearing of a pessary. Assuming for a moment safety and certainty of result the position is this:—One patient is brought into hospital on account of menorrhagia. She has a backward displacement. She is curetted and a pessary is inserted. Her stay in hospital varies from a couple of days to a week. She then leaves, but has to return at least every three months to the extern department to have the pessary removed, cleaned, and replaced. No matter how well it fits, it may at any time cause irritation and discharge from the vagina. It may even cause ulceration of the vaginal walls. If a large pessary has to be used it stretches the walls, and on account of this stretching its size has probably to be increased progressively. In old age it is certain to cause even more marked discomfort.

Contrast this with the history of another patient, who comes into hospital under similar conditions, and on whom a radical operation has been performed. Her stay in hospital is from ten days to a fortnight. She leaves unaccompanied by a pessary, and, so far as the uterine displacement is concerned, there is no

The only way one can decide as to the safety and certainty of the different radical operations is by examining into their immediate and subsequent results, and it is for this reason that I wish to-night to place before you a short criticism of radical operations, and especially of the method I usually adopt in these cases and its results.

I had better begin by dividing the cases in which radical operations are necessary into three groups:—
(1) Cases in which a major operation has been per-

formed and the peritoneal cavity is opened. Cases in which the displacement is complicated

by adnexal disease.

(3) Cases of uncomplicated backward displacements. The cases in the third groups are those with which I am principally concerned, and I can dispose of the first two groups in a few words.

When an abdominal operation has been performed, such as myomectomy or operations on the appendages, I always finish the operation by performing ventro-suspension of the uterus by Kelly's method, and, if the patient is likely to have children and the operation has not taken a long time, I like to supplement it by the intra-peritoneal shortening of the round ligaments. The reason for the latter step is that the adhesions formed by Kelly's operation always tear away or stretch during pregnancy, and that there is nothing to prevent a return of the displacement after delivery, if the uterus is inclined to fall back.

When a displacement of the uterus is complicated

by adnexal disease it is necessary to open the peritoneal cavity for the treatment of the latter condition, and then these cases fall under the same rule as those in the first group.

This brings us to group three and to the question, What is the best operation for the radical cure of uncomplicated backward displacements of the uterus? There are three different classes of operation:

(a) Ventral fixation or suspension of the uterus.(b) Vaginal fixation of the uterus.

(c) Operation on the uterine ligaments.

Ventral fixation of the uterus is not permissible during the child-bearing period, because it causes too strong a bond of union between the uterus and the abdominal wall. Ventral suspension, on the other hand is always permissible. Its immediate results are uniformly good, and if the uterus and its ligaments return to a normal state, the results after pregnancy are also good. It, however, affords no support what-soever after pregnancy, because the essence of the operation is the formation of a bond of union which will tear away or elongate during pregnancy and so permit uterine development. I am aware that there is a difference of opinion on this point, and I was once told that if I could not get the uterus to remain in position after pregnancy in cases in which I had performed Kelly's operation it was because I had performed the operation wrongly. The speaker, indeed,

went so far to say that if I had in the past used only one fixation stitch I should in the future use two, and if I had used two I should in future use three. Such a remark applies very correctly to a ventral fixation, but not to the suspension operation. Howard Kelly, who originated the operation, writes thus:—
"After labour the malposition of the uterus may return. Fourteen cases upon which suspensory opera-tions have been performed at the Johns Hopkins Hospital have been examined at varying periods after labour. In nine of them the uterus was in good anteposition, while in five the ligaments had apparently broken and the uterus was again in retroposi-I have only one criticism to make on this remark, namely, that I am inclined to think that the normal position of the uterus in the nine cases was due, not to the persistence of the false ligament, but to the fact that the uterus and its true ligaments had returned to a normal condition. I have not looked up my own statistics, but I know I have had some half-dozen cases in which pregnancy has occurred after Kelly's operation, and the proportion of returns is about similar to that given by Kelly. In one case I subsequently opened the abdomen and there was no trace of the suspensory ligament. Further, I have never heard of an operator who has found a sus-pensory ligament in any case in which he opened the abdomen of a patient who had become pregnant after a Kelly's ventral-suspension.

Vaginal fixation of the uterus I, personally, do not like, and I think neither do most other gynæcologists. It is a useful substitute for ventral fixation in some cases, but not for ventral suspension. I thought at one time that the difficulty which it causes during pregnancy might be avoided by passing the fixation sutures low down on the uterus near the corporocervical junction. This practice, however, is useless when the uterus is large and the vagina lax, as it means that the upper part of the vagina is dragged over by the heavy uterus and the displacement recurs,

even though the fixation persists.

The third class of operations-namely, operations on uterine ligaments-includes the operation which I think is that of choice in uncomplicated displacements of the uterus. I will not weary you by discussing all the different forms of operation which have been suggested on these ligaments, their name is legion. The sacroiliac ligaments have been shortened through the vagina and through the abdominal cavity, and the practice is often a useful one in severe cases of prolapse. The round ligaments have been shortened at the external abdominal ring, and intra-peritoneally, through single incisions and through double incisions. They have been tied in knots in front of the uterus and behind the uterus. They have been pulled through openings in the abdominal wall and through openings in the vagina. Still, when every possible commutation and permutation of the original operation has been adopted, we are brought back, I think, to where we started, and to the fact that the original operation is the best and

The original operation for the shortening of the round ligaments was first placed on its present basis by Alexander, of Liverpool, and is now known by his name. It is said to have been introduced by Alquié, of Montpellier, in 1840, who, however, only performed it on animals. It was condemned by a Commission appointed by the French Académie de Médecine, and apparently died. In 1864 it was performed for the first time on a human being by Deneffe, and in 1881 it was again introduced by Alexander, to whom the credit of its existence as a well-recognised operation is undoubtedly due. In 1882 it was performed by Adams, who had previously practised it on the cadaver, and had taught it to his class. Owing to the multiplicity of parentage it is consequently sometimes known as the Alquié-Alexander-Adams operation.

As is well known, the operation consists in drawing out the round ligaments at the external abdominal ring, cutting off the excess, and anchoring the stump to the pillars of the ring or the sides of the inguinal canal if the latter has been opened. As an operation it has had a chequered career, not the least curious feature of which is its almost complete rejection by the coun-

tries in which it was originated. Not alone did the French Commission condemn it in 1840, but it was almost universally rejected by English gynæcologists after Alexander introduced it. Gradually it established a firm position in America, and now it is recognised by gynæcologists all over the world, with a few exceptions, as being a valuable operation.

Even at the present day, however, it has the virtue of causing an extraordinary difference of opinion on points which one would have thought impossible.

In a work on gynæcology published in 1907, Herman writes that "the grave objection to Alexander's operation is its risk; the danger to life and the danger of a long illness with suppuration of the wound. . . This detachment (of the ligaments), together with the tension which is put upon them, seems to lower their resisting power and make them liable to inflammation. This inflammation may lead to deep suppuration, which may spread to the peritoneum, and thus fatal peritonitis follow in a week or so after the operation."

In a similar work published in 1903, Galabin writes In a similar work published in 1903, Galabin writes that "the operation has a particular liability to be followed by suppuration of the wound." On the other hand, Noble, in 1907, states that "the mortality of Alexander's operation is practically nil. In my experience there have been no deaths"; and Taylor, of Birmingham, in the same year recorded 85 cases without a death in a paper which may be taken as a practical answer to Herman's statement that in England he "knew of no operator, except Dr. Alexander, who has performed the operation often enough to make his experience representative of the average results in the

perience representative of the acting hands of a competent operator."

So much for the objections to the operation on the ground of safety. On the ground of efficiency, so far as I am aware, there is no difference of opinion. Even those who say that it is dangerous admit that it is efficacious. All Taylor's cases were successful. Peterson operated 56 times, with no relapses that he knows of. Noble had one failure and one partial failure in about 200 cases. I will give my own statistics later.

A third objection which may be raised is that of difficulty. It is an undoubted fact that in some cases it is hard to find the ligaments, and that in others they break as they are being drawn out. The number of these cases is very marked when one begins to practise the operation. It gradually lessens very considerably, but never quite disappears. Its importance is, I think, over-estimated. One first looks for the ligament at the external abdominal ring. If it cannot be found there, one opens the inguinal canal. If it cannot be found there, or if it breaks, one deepens the incision and opens the peritoneal cavity. The ligament is then found and drawn out. If we remember that of the various structures coming through the external ring the ligament

lies deepest and lowest, we shall seldom fail to find it. I have nothing to say regarding the lechnique of the operation, save that, although in most of the cases recorded below double incisions were made, I have lately adopted the single transverse incision, and I think it is quicker. There is, however, no material difference between the two. As regards the after-treatment, I differ in one point of practice from almost everyone whose opinions I have read. Taylor may be taken as voicing these opinions when he says that he inserts a pessary and usually keeps it in place for three months after the operation. On this point I have only to say that I have never yet inserted a pessary even for a week, and that I see no object in doing so. I think my statistics show, so far as a small number of cases go, that it is unnecessary.

My cases and their results may be summarised as follows:-Forty-four cases were operated on. In 39 the usual double incisions were made, and in 5 a single incision was made. There were thus 83 separate incisions, and every one of these healed by primary union. One incision subsequently suppurated sub-cutaneously owing to the fact that the subcuticular suture broke during removal and was left behind,

One patient died, but her death, which was from double croupous pneumonia, cannot, I think, be attributed to the operation. The symptoms of pneumonia appeared in one lung on the fifth day after the operation. My colleague, Dr. Hayes, very kindly looked after her for me, but, in spite of everything, the second

lung became involved, and she died on the eighth day after operation. The incisions had apparently healed normally.

In one case the uterus subsequently fell back. This was one of the first cases on which I operated, and on making the first incision on the right side I could not find the ligament. Consequently I opened the peritoneal cavity and drew the ligament out and fastened it. As, in addition to this, I had already curetted the uterus, performed a double trachelorrhaphy, and ligatured piles, the operation had lasted sufficiently long, and consequently I did not operate on the left ligament. The uterus was thus suspended by only one ligament. In spite of this, the uterus was in good position when the patient left the hospital 17 days later, and was also in good position six months later. The patient, however, returned two years later, and the displacement had recurred.

In two cases the patients were subsequently delivered under my care. On examination a fortnight or so after the delivery the uterus was found to be in a normal position.

In conclusion, I should like to state shortly why I consider that Alexander's operation is the operation of choice in uncomplicated cases of backward displacement of the uterus. To my mind the only operation which comes into competition with it is Kelly's method of ventral suspension. If there is any appreciable element of risk attachable to either operation, I think that it attaches itself more strongly to the operation which necessitates the opening of the peritoneal cavity, and that if both operations are equally suitable, the one which does not necessarily involve such an opening is the one to select. Further, I think that Alexander's operation is more likely to lead to permanent results after parturition, though I quite recognise that it is not infallible. The false ligament formed during Kelly's operation must either stretch during pregnancy or break. If it stretches it must practically extend from the symphysis to a little below the ensiform cartilage. It is only a peritoneal band, and to expect it to contract again to such dimensions as to exert a restraining influence on an unimpregnated uterus is to expect too The round ligament, on the other hand, undoubtedly possesses the power of contraction, and normally elongates during pregnancy and again returns to its former length. We can, therefore, look forward with some degree of confidence to the shortened ligament involuting after pregnancy to an extent which will again enable it to exert a restraining effect on the movements of the fundus.

The Kelly operation possesses one advantage, namely, that it enables one to inspect the uterus and pelvic organs generally during its performance, and so to make sure that there is no adnexal disease. Alexander operation, on the other hand, compels one to depend on the results of a bi-manual examination. In this respect the question becomes one of diagnosis. Alexander's operation is only suited for uncomplicated cases. If there is any doubt as to whether the case is or is not uncomplictaed, by all means give the patient the benefit of it and perform Kelly's operation. So far as my own experience goes, however, it is only in a small percentage of cases that such a doubt exists.

The difference between extra-peritoneal and intraperitoneal shortening of the ligaments is that after extra-peritoneal shortening the uterus is held by the extra-peritoneal shortening the uterus is need by the strongest proximal portion of the ligament, while after intra-peritoneal shortening the uterus is held by the weak distal portion. For this reason the former operation is much more satisfactory.

I began this paper by saying that, provided operative procedures are safe and give a good after-result, they are preferable to the prolonged wearing of a pessary. I have quoted statistics, including my own, of 385 cases, amongst which there were, so far as is known, about three failures and one death. The latter was due to croupous pneumonia, and save that it occurred after the operation had no other connection with it. I think, therefore, we may consider that Alexander's operation affords a certain and safe cure of all uncomplicated cases of backward displacement of the uncourse and that it artists and the items. of the uterus, and that it entitles us to advise opera-tion in all such cases which require treatment.

#### SHRAPNEL WOUNDS.

By Marine-Oberassistenzarzt Dr. SCHEEL.

On August 21st, 1907, at the Artillery Depôt, Wilhelmshaven, twelve men and two women were engaged in a wooden shed resting on a stone basement in emptying and cleaning 15 cm. shrapnel During the process twenty of the shells exploded, causing such injuries as would be likely to be numerous in any future war, so that the publication of the cases seems to be of general publication of the cases seems to be of general interest. Of the 14 engaged, '5 were killed outright, 3 were seriously injured, 3 slightly, and were taken to the dockyard hospital; the remaining 3 were working farther away and saved themselves by a rapid retreat. The five immediately killed had the following injuries:—(1) Workman L. From the trunk almost the whole of the anterior abdominal wall from the breast to the symphysis publis minal wall from the breast to the symphysis pubis was torn away, and from the crest of one ilium to the other. The abdominal contents, especially loops of intestines, were protruding. (2) Workman W. Almost all the anterior half of the skull and the greater part of the face as far as the upper lip were missing. Pieces of bone, remnants of brain, and blood clots lay in the opened skull. Of the left arm only a stump 20 cm. in length remained. On the right hip the skin was entirely gone from an almost circular space 20 cm. in diameter. (3) Workman W. Here was a widely gaping rent from the top of the head to the middle of the left side of the neck, 2 cm. in width, through both the soft parts and the bones of the skull, so as to admit a view into the cavity of it. Half of the brain was The face was so much torn as to be missing. unrecognisable. The right arm was torn from the shoulder-joint. On the lower part of the leg and the remains of the thigh charred remnants of bone and of the soft parts were seen lying. (4) Workman R. Right arm torn to shreds and the bone shattered. The skin was missing both over the back and the abdomen, all the deeper-lying soft parts were in shreds and the bones broken up. The vertebral column torn apart. The left lower extremity was torn from the trunk. (5) Workman F. A gaping wound 12 cm. in length was present on the outer side of the left arm, in which lacerated soft parts and fragments of the bone of the arm were visible. The right hand torn to shreds. On the right leg was a wound 10 cm, in length in which were to be seen the lacerated soft parts and the shattered stumps of the bones of the leg. On the left leg were several openings the size of tenplennig pieces, through which soft parts soaked in blood were protruding. Several shrapnel balls were lying in the exposed cavities of the bodies, in the wounds on the extremities, and in the clothing. Two women and one man were brought in seriously injured, the latter dying of his injuries six days later. They were:—(i) Workman M. The hair was singed off and there were burns on the head and face. Œdema of the eyelids. Burns on the left shoulder, the left upper and forearm and hand. The right hand and forearm were less seriously injured. (2) Workman F. (Burst out into flames at once, and had sprung immediately into a trench of dirty water near by.) The clothes dripping with mud; on removal of the clothes several blisters already burst and very much soiled The hair badly singed. Extensive were found. burns on the head, neck and face. The right arm badly burnt, the skin of the hand torn off into shreds, the bones of the index finger broken to Burns on the left arm, the chest and back. (3) Workman O. (Had at once fallen down, and had had elastic rubber bandages applied to both

thighs on account of arterial hæmorrhage.) The right leg was broken in two places, the soft parts lacerated, with violent hæmorrhage. The left leg was also broken, but with only slight hæmorrhage. The cardiac sounds feeble, pulse small, rapid. Amputation of the right leg below the knee. Death on the sixth day from cardiac weakness. The autopsy showed that the right fibula was split high up. There were also three with slight injuries

up. There were also three with singlify described the manifold injuries described the manifold with those of the Russo-Japanese war, we find the reports from injuries from artillery missiles everywhere the same. These wounds are described as most dangerous and frightful. We hear of people who have been so much shattered that only small portions of their bodies have remained; we read of one man who, from the explosion of a shot of large calibre, received not less than 160 wounds, that immediate amputation of limbs was necessary in a large number of troops, and that non-penetrating as well as penetrating ones were almost always complicated by fractures of bones. What horrible devastations are produced by the fire of such weapons is shown by the reports of the wounded of the Warjag, in which, after a fight that lasted half an hour, thirty were killed and seventy wounded. Withal, it is always noticed that shrapnel wounds are almost always infected, as the bullets and fragments of exploded shell almost always carry dirt and particles of clothing with them into the tracks of the wounds. In wounds of this kind the prognosis is therefore very bad. In the bursting of a shrapnel the individual bullets take a course that varies very much, and the rotation of the shell as a whole communicates a centrifugating effect to the bullets with which it is charged. The way in which the balls and exploded fragments fly apart has been likened to the rose of a hose-pipe in which the water is forced outwards from hundreds of openings. But if the rose is also made to rotate rapidly, and when we consider that the bursting charge of every shell adds considerably to the velocity, we shall get an idea of the indeterminate direction taken by the individual parts and of the gravity of the wounds caused by them. Very severe injuries were caused here as well as there by the gases and flames of the exploded shells, the flames reaching mast-high. Similar intense burnings of the skin were reported, for example, from the fight at the mouth of the Jalu, where of the 289 killed and wounded Japanese, 57 men showed burns that extended over more than a third of the whole surface of the body. There were also cutaneous injuries from the burning gas from the powder, principally in the case of shells that, like the shrapnels, were still charged with black powder. They were caused by the hot granules of powder penetrating the skin like fine shot.

#### CLINICAL RECORDS.

#### SARCOMA OF THE MESO-SALPINX.

By F. J. McCANN, M.D., F.R.C.S.ENG., Physician, Samaritan Free Hospital, etc.

THE sarcomatous tumour was removed by Dr. Frederick McCann in May, 1908. The patient, a widow, æt. 52, was extremely feeble and emaciated. Her menstrual periods had ceased for two years, but in October, 1907, she commenced to lose blood from the vagina, which alternated with a yellow-green discharge. Latterly she complained of abdominal pain, swelling and sickness. She was steadily losing flesh and rapidly becoming more anæmic. She had had three children, the youngest being aged 26 years, and for 20 years she had been a widow.

(a) Notes of a case read at a meeting of the Gynmoological and Obstetrical Section of the Royal Society of Medicine, Feb. 11, 1909.

Her abdomen was distended and tender on palpation, but a distinct elastic tense tumour reaching to the level of the umbilicus could be detected rising out of the pelvis. The uterus, which was not enlarged, was situated in front and to the left of the pelvic portion of the tumour. Malignant ovarian disease was diagnosed and operation recommended. The tumour when exposed was found to be of a deep livid colour with omentum and intestine adhering to it, whilst the peritoneum was thickened and ædematous. The adhesions were separated and ligatured, and a quantity of blood clot was removed from the abdomen. The pedicle, which was narrow, was secured by separate ligature of the vessels and subsequent covering with peritoneum. The body of the uterus was not enlarged, and the appendages on the left side also appeared to be healthy. The operation was done rapidly on account of the feeble condition of the patient, but her further improvement was most marked. The wound healed well, and all the stitches were removed. Her friends were amazed at her rapid progress. This, however, was short-lived, for on June 14th, sixteen days later, a change for the worse occurred.

The abdomen was distended, especially on the left side, and impaired resonance was elicited in the left flank. She was very anæmic and extremely feeble. The radial pulse was rapid and badly filled. The abdomen was accordingly re-opened, and the peritoneum found to be still more thickened and gelatinous, several veins requiring to be ligatured in the abdominal wall. There were most extensive intestinal adhesions, which entirely prevented access to the swelling on the left side of the abdomen, which appeared to be composed of matted intestine. Some dark sanious fluid was evacuated from the peritoneal cavity.

As complete removal of the disease was impossible, the abdomen was at once closed. After this operation her feebleness gradually increased and she died five days later.

Permission could not be obtained to have a postmortem examination, and thus the opportunity of verifying what really had occurred was lost.

The tumour when removed measured 7 in. by 4½ in. at the widest end, and 2½ in. in thickness. It was of an irregular ovoid shape, and consisted of two distinct portions. The outer or ampullary half was soft and contained blood clot, whilst the inner or uterine half was firm. This portion was deeply stained with blood pigment, fibrous in appearance, with paler areas scattered through it. The lumen of the tube could be traced running across the mass. Microscopically the growth was found to consist of rounded and oat-shaped nucleated cells, invading the muscular wall of the tube. The blood vessels were represented by channels in the midst of the tumour tissue. There were no epithelial elements and no giant cells. The amount of blood pigment was a conspicuous feature in the sections.

If the nature of the growth had been known at the first operation the proper treatment would have been to remove the uterus, tubes, ovaries and broad ligaments in one piece.

The uterus, although not enlarged, might have contained new growth in its interior, but, if so, it must have been very small. When the tumour was first examined it was thought to be a primary sarcoma, commencing in the muscular wall of the Fallopian tube. Subsequent investigation, however, showed that the unaltered tube could be traced over one surface of this mass, and that the growth had, apparently, originated in the cellular tissue of the mesosalpinx.

#### **OPERATING THEATRES.**

ST. THOMAS'S HOSPITAL.

PYÆMIA FROM ACUTE BONE DISEASE DUE TO
INFECTION WITH THE STAFHYLOCOCCUS AUREUS.—
RECOVERY.—In showing this case, done eight years
ago, Mr. Corner said: This healthy young man, a

plumber by trade, was then æt. 17, and was taken ill with sickness,, headache, chills, and pain in the left leg in 1902. His medical attendant found his temperature during the first fourteen days to vary between 104.8° and 101.8°. On admission, the patient was obviously very ill; he complained of little pain, and his tongue was fairly clean considering the length of his illness. His temperature was 101.6°. He had swellings in the neighbourhood of many joints, with a soft systolic murmur at the apex of heart, which had led to a diagnosis of rheumatism. A follicular rash was present over the chest and abdomen. An anæsthetic was given, and incisions were made into two large subperiosteal abscesses on the internal surface of the left tibia and one of the right tibia, a large abscess over the lower end of the left fibula, another over the left olecranon, the left elbow-joint, the right knee-joint, the left sterno-clavicular joint, and the right sterno-maxillary joint. All the joints contained pus, and at the bottom of the abscesses bare bone was exposed. The lower part of the left fibula was divided and twisted off its lower epiphysis. The bov was very ill and the incisions were made hurriedly. When he was bandaged up fluid was found in the left knee-joint into which a trocar and cannula were left knee-joint into which a trocar and cannula were plunged. The fluid which was withdrawn gave a pure and copious culture of the staphylococcus pyogenes aureus. On the day after operation his temperature rose to 103.8°, the pulse being 116 and the respirations 32. On the next day his temperature was 100.6°, pulse 105. He was eating well and feeling better. All the wounds were discharging well. He was not so well on the following day, and on the fourth day his temperature had risen to 102.4°, later fourth day his temperature had risen to 102.40, later reaching 104.4°; pulse, 130. A large abscess was opened in the right buttock. From the 6th to the 28th day he improved slowly. His temperature varied from 101° to 104.8°, making daily excursions of 3-4 degrees. But his appetite was good, he had no diarrhœa, and the wounds were cleaning. pulse varied from 100 to 148, and his respirations from 24-38. He was treated and the wounds dressed on ordinary lines. No special treatment or serum was given. On the 32nd day his temperature had been slowly descending by lysis, accompanied by diarrhæa, two to six copious and offensive stools being passed daily. An atempt was made by the house-surgeon to remove the sequestrum from the upper part of the fibula. He failed to do this and sewed the wound up. Strange as it may appear, the operation was done on a very septic man in septic surroundings, but the wound healed by first inten-Superficial sequestra came away from the surface of the tibia and other situations. At a later date the fibular sequestrum was removed and the wound sewn up, which again healed by first intention. Throughout a whole month his temperature never came below 100°, ranging from thence to 102°. The diarrhæa noted to have commenced with the decline of the temperature continued throughout the month, 2-6 stools being passed daily. An enema was given during this period with the view of relieving his discomfort. The temperature immediately rose to 103.8°, the pulse to 140, and the diarrhea increased for the next twenty-four hours. The diarrhea was treated by drugs given by mouth, which produced little or no effect upon it. During the following little or no effect upon it. During the following month the temperature still further declined, ranging from 99°—100°, and thence slowly becoming normal.

The diarrhœa declined with the temperature. On the 96th day of residence in hospital the patient was able to walk, and was discharged to a convalescent home.

Mr. Corner wished particularly to direct attention to the following points:—(1) The boy, having been poisoned for 16 days before admission by the staphylococcus pyogenes aureus, recovered. Presumably, therefore, the infection was not the most virulent. (2) Nothing more than ordinary surgical and medical treatment was adopted. (3) The joint, which was only aspirated, and from which the staphylococcus was obtained, never filled with fluid again. (4) On two occasions operations were done on a septic boy in septic surroundings, and the wounds united without a

trace of inflammatory reaction. Presumably the boy, having recovered from the infection, had manufactured his own anti-toxin, and hence it would have been very difficult to make any wound in him sup-purate. The behaviour of the wounds agreed with that of the knee-joint which was aspirated. (5) The diarrheea was obviously the result of a septic enteritis. and prolonged his convalescence. (6) Enemata raised a "storm" when used to relieve the diarrhea, for which drugs and diet were the far better treatment.

FEB. 24, 1909.

PERIGASTRIC ABSCESS, Pyloric OBSTRUCTION, URGENT GASTRO-ENTEROSTOMY.-MR. CORNER operated on a man, æt. 32, with a history of symptoms of gastric ulcer for six months. The patient had been worse for a fortnight, with epigastric pain. On admission he was a thin man, with a swelling in epigastrium, and rigidity of belly wall over it. There was transmitted pulsation and tenderness, with a sense of indefinite fluctuation. The temperature for four days after admission was about 99° to 101° on day of operation, gradually rising. An incision was made through the left rectus above the umbilicus. The general peritoneal cavity was not opened. An abscess was struck at once, which contained about a couple of drachms of thick, white, odourless pus. Film and one ærobic and one anærobic culture from the pus. A drainage tube was inserted. The man improved since this operation, but developed a gastric fistula. After a time the improvement became stationary, and it was increasingly evident that the contraction of the scar tissue of the walls of the abscess were producing pyloric obstruction. It was therefore necessary to do something to relieve the man, with which object he was again brought to the theatre. After the anæsthetic was administered and the abdominal wall cleansed, an incision was made through the upper part of the left rectus to the left of the scar of the former operation. When the peritoneum was opened, it was found impossible to do more than bring a small portion of the stomach to the surface. Owing to the short duration of the obstruction, the stomach was little dilated, and the adhesions of the perigastric abscess prevented its being brought out of the wound. It was necessary, in consequence, to do an anterior gastro-enterostomy. A posterior gastro-enterostomy, Mr. Corner pointed out, was a far better operation in these gastric ulcer cases, and the operation for choice. In this case there was no choice, and an anterior gastro-enterostomy was done by suture. The operation was difficult and tedious. The abdominal wound was closed in layers without drainage.

Mr. Corner remarked that it was very unusual to do an urgent gastro-enterostomy. Such cases could usually wait. But in the present instance there was the un-usual combination of severe stenosis, whilst the stomach had not had time to become dilated. In consequence the man was unable even to take water by mouth. The intake of water is extremely important in these cases, which at times die from lack of water. The most marked instance of the kind Mr. Corner had ever seen was a girl of 20, who had incessant sickness a week after an operation for appendix abscess. Examination of her abdomen did not confirm a diagnosis of intestinal obstruction, or of peritonitis. If this was or mestinal obstruction, or of peritonitis. If this was true "lack of water" might be causing the trouble. The temperature was 96.5°, and the pulse uncountable. Her hands were cold and clammy. Half-a-pint of warm saline was given per rectum. At the end of halfan-hour the girl was no worse, so another half-pint was given, and half-an-hour later the girl seemed a little better. The treatment was pursued, and she had a pint given hourly for ten hours. The result was that she rose from the grave, though her friends, relations, and doctor had regarded her death as inevitable.

Now in this man's case rectal feeding might have been resorted to, but he could not retain the feeds. In consequence, the gastro-enterostomy had to be done without delay. And, as pointed out, this was a difficult operation.

#### TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

MEETING HELD FEBRUARY 11TH, 1909.

The President, Dr. HERBERT SPENCER, in the Chair. DR. F. J. McCann read a short communication on SARCOMA OF THE MESO-SALPINX,

which will be found on page 189 of our present issue. Dr. HENRY RUSSELL ANDREWS read a short communication on some cases of ovarian cysts associated with vesicular mole. He gave an account of four cases that had been under his own care:-(1) A case in which a lutein cyst tumour with twisted pedicle was removed after the passage of a vesicular mole. (2) A case in which bilateral lutein cyst tumours, one with a twisted pedicle, were removed 17 days before the passage of a vesicular mole. (3) A case in which small bilateral ovarian cysts, both suppurating, were removed after the passage of a vesicular mole. (4) A case in which a small ovarian tumour was found, while a mole was being removed from the uterus. This tumour became smaller gradually, and the ovary eventually returned to its normal size. He suggested that small ovarian tumours found in association with vesicular mole should not be removed unless they showed signs of twisting of the pedicle or suppuration. He quoted two other recorded cases in which ovarian tumours found at the time of expulsion of vesicular moles were noticed to become smaller and smaller, until eventually no enlargement of the ovaries could be made out. gave a brief resume of some of the recent work on the functions of the corpus luteum.

Dr. G. F. BLACKER read a paper on a case of HYDATIDIFORM MOLE WITH ALBUMINURIA AND THE KIDNEY OF PREGNANCY — SUDDEN DEATH FROM CARDIAC FAILURE.

The patient, a woman, æt. 33, was admitted into University College Hospital on July 18th, 1908. On admission the patient was about 19 weeks pregnant, and for a few weeks had noticed some swelling of the eyelids and ankles, and some hæmorrhage had occurred from the uterus. The urine contained 50 per cent. of albumin, with hyaline and granular casts. She was placed on a strict milk diet, and the albumin became much less abundant. She was found, however, to have well-marked signs of albuminutic retinitis. August 17th and 19th there were severe hæmorrhages from the uterus, and the vision was deteriorating. was therefore decided to induce labour. Bougies were introduced on August 21st, and the cervix began to open up, but early on the morning of the 22nd the woman suddenly became collapsed, fainted, and died in a few minutes. A post-mortem examination showed that the liver was somewhat enlarged, and showed cloudy and fatty changes in its cells. The kidneys were also a little enlarged, and the cortex a little paler than normal. The uterus reached nearly to the ensiform cartilage. Microscopic examination of the kidneys showed marked cloudy swelling and coagulation, necrosis of the epithelium of the convoluted tubules and glomeruli. The ovaries were occupied by a number of cysts mainly derived from the corpora lutea, and they definitely contained an excess of lutein tissue. If we consider for a moment the changes which occur in the mole and in the ovary in cases of resicular degeneration of the chorion, we cannot but be struck by the marked similarity between them. In the mole we have an excessive proliferation of the epithelium of the villi with the formation of cystic spaces, no doubt due to a serous transudation, while in the ovary we have a marked proliferation of the cells of the corpora lutea with the development of cysts possibly of similar origin. Does not this similarity suggest that the same cause, whatever it may be, is acting in the two cases, and more especially when we remember that an excess of lutein tissue is found to accompany normal pregnancy. I do not think the lippothesis that an excess of lutein tissue plays an important part in the causation of the overgrowth of the epithelium of the villi is by any means proved.

THE LORD MAYOR has consented to open the new pathological block of St. Bartholomew's Hospital on Friday, May 7th, at 3 o'clock.

The PRESIDENT (Dr. Herbert Spencer) said that he had long thought that a great deal too much importance was being given to these so-called lutein cysts. When one remembered the frequency with which cysts of the corpus luteum are met with both in the unimpregnated and the pregnant, and the large number of hydatidiform moles which have been removed in the part without the subsequent development of ovarian tumours, he thought that lutein cysts might, in many cases, at all events, be left alone.

Dr. CUTHBERT LOCKYER said that the points definitely known about these compound lutein cysts were that they were possessed of strikingly characteristic features, both to the naked eye and on microscopic examination; secondly, that they were never found excepting in association with vesicular mole and chorion-epithelioma. The point yet to be decided was: What relationship do these ovarian and ovular changes bear to each other? The time had not arrived when this difficult point could be settled. He referred to the occasional disappearance of lutein

Mr. J. H. TARGETT referred to a case where he had performed a double ovariotomy during pregnancy, and the tumours removed were typical lutein cysts. The patient subsequently miscarried and expelled a macerated fœtus. On careful examination it was found that a small portion of the placenta was mingled with the cysts of a vesicular mole.

Dr. R. H. PARAMORE suggested that the underlying cause of the clinical signs found in Dr. Blacker's case was a mechanical one, and referred to the views of Ahlfeld on the causation of eclampsia.

#### ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

MEETING HELD FRIDAY, FEBRUARY 5TH, 1909.

The President, W. R. DAWSON, M.D., in the Chair.

THE PRESIDENT read a paper entitled "The Irish Recommendations of the Royal Commission on the Care and Control of the Feeble-minded," in which he gave a short acount of the chief recommendations. In the discussion which followed—

Mr. Louis Kelly, B.L., said he was astonished that such a revolutionary report was so little known and the extent of its recommendations so little appreciated by those who professed to take an interest in the subject. At a recent meeting of a philanthropic society in Dublin a resolution was proposed asking for a grant, the purpose of which was adequately met by the recommendations before them; and at the meeting at which that resolution was proposed, while other Royal Commissions were referred to, the newspaper report was silent as regards the Commission which they were now discussing. In criticising the recommendations he wished to point out that while past and present inspectors of lunatics were exclusively medical men, there was no provision in the law as it stood that those posts should be compulsorily arrogated to medical men. In England there were legal inspectors who had done good work, and he objected to the ex-clusiveness of the recommendations in that respect. The recommendations also proposed to make manent the present local committees who controlled the asylums in the country. He had no great venera-tion for a scheme by which so much control and authority was vested in men who had absolutely no training or qualification for the duties imposed on them. Such committees had done, and were doing, things which no person who was interested in the well-being of the insane could justify. Their very irresponsibility might be taken as an excuse for acts of which he would give some examples collected at random, and in which violence to patients under circumstances which gave no justification for it, and committed by men who were notorious for assault even outside the asylum, was condoned. The President had indicated another weakness in the scheme in regard to the course to be adopted when money was sought to be obtained for building purposes. He objected to the proposed multiplicity of control which only perpetuated one of the fatal defects of the present lunacy system of administration in which there were nine bodies which had a certain amount of power and He could not, however, conceal from himauthority. self that the Report was a marked advance, and its generosity towards Ireland was one of its outstanding characteristics. In the special grant for the provision of necessary accommodation it went further than it did in respect of England or Wales. He hoped the recommendations of the Report would become more generally known, and to some extent carried out, and that it would not be pigeon-holed, like the recommendations of the Vice-Regal Commission on Poor-law in 1891, and others, which proposed the most salutary changes.

Dr. LEEPER said the subject of the care of the feeble-minded and the degenerates of the country was inseparable from Poor-law reform, and the latter would have to come first. In the workhouses, as at present constituted, all the factors that made for degeneracy in the population were being run by State aid. If they reformed the workhouses they would prevent the propagation of degenerates and control the feeble-minded. The speaker said he was old enough to have given written and verbal evidence before the Committee appointed by the Lord Lieutenant of Ireland, the Lunacy Administration, whose report was issued in the year 1891. The recommendations of this Committee were pigeon-holed and were never given any effect to, because they ignored the legal difficulties of the subject, and nothing had been done since to alter or amend the Irish Lunacy Laws. The chief difficulty would be in controlling the feebleminded, who numbered twice as many as the idiots and imbeciles together, and who were capable of doing much more injury to the race than the latter. would be regrettable if they had to depend for the control of the demented and degenerate on the will and whim of Justices of the Peace, one of whom had refused to commit an obvious lunatic who the next day killed a farmer.

Dr. M'VITTIE said the question of teachers for the feeble-minded was a central point. He was of opinion that there were immense numbers of feeble-minded adults who never should have been so. He was satisfied that there were many children in whom intelli-gence developed late, and that such children, if suitably handled by properly trained teachers, might become useful members of the community. Most of them were ruined in school. Nine out of ten of the teachers under the National Board had nearly all the qualities required to make successful teachers destroyed before they were launched. Their nervous systems were ruined, and their capacity to deal with neurotic or delicate children eradicated. He had examined many such teachers. They were excitable and neurotic, and had been worn and worried by studying a great deal of rubbish for examinations. They would be getting something done if they pressed on the Government the importance of selecting teachers with greater care as regards their physical training. propagation of degenerates extended beyond the workhouses. There were children in large towns who were reared in unfortunate circumstances as regards health, and if they were to be sent to schools with long hours he was afraid they must have an ever-increasing ratio

of feeble-minded people.

Miss Buchanan, P.L.G., said she felt deeply the necessity for Poor-law reform, and at the same time trusted that the recommendations of the Commission would meet with attention. The Vice-Regal Report, if carried out, would do much to reform the present shocking state of the workhouses in Ireland, and the with the feeble-minded. The Poor-law dealt with destitution, but the feeble-minded and defective need not be destitute in order to be a source of injury to the community. The public did not know that there was only the Stewart Institution to which an imbecile child could be sent, and there were cases constantly coming before her Board of Guardians in which people not absolutely destitute begged that an imbecile

child should be sent to the Institution. But because the Stewart Institution had come to be regarded by Catholics as an unsuitable place for their children, such children could not be sent anywhere but to the wards of a workhouse. Even a child sent to an English institution had been brought back because it was found that she was of Catholic parentage. There was no place for sane epileptics except the workhouses. The whole subject called loudly for legisla-The recommendations of Royal Commissions were important, but they were no use if they were pigeon-holed.

Dr. Colles said the legal difficulty was illustrated in the recommendation, that the statutory committee of a council, if it did not like the guardianship of a child, could constitute itself the guardian of the child. That had struck the Commissioners as strong, and they provided an appeal to a Court of Summary Juris-diction, and if anyone was dissatisfied with that they could go to the Judge of Assize. He suggested to the Commission that a better plan would be to vest in the County Court Judge the power of appointing a guardian, not only of a child, but of a feeble-minded adult, and power to define the powers which the guardian should exercise over his ward. The Commissioners seemed to be inspired by the idea that if they could get a designation that would not but they could get a designation that would not hurt people's feelings, opposition would be disarmed, but he thought the associations of the term "mentally defective" would ultimately become as objectionable as the terms "lunatic" and "insanity," which were not originally opprobrious.

The President said he was of opinion that the ideal method of dealing with the feeble-minded and every other class of mentally defective, would be to make the whole thing a national service like the Army Medical Service. He thought, however, that it would now be impossible to get rid of the control of the County Councils, and that the recommendations provided for their proper subordination to the central authority had the power to stop the grant if every-thing was not satisfactorily carried out. The number of defectives in workhouses was very large, and the treatment of their mental condition was about as bad as it could be. Many inmates of prisons were drawn from the feeble-minded; almost always they became alcoholic when thrown into criminal associations, and speedily went from bad to worse. The average of previous convictions for Dublin defectives-who constituted 11 per cent. of the inmates of the prisons—was nearly 18. Such facts showed the necessity for interference, and one of the advantages to be derived from any far-reaching system of control would be the placing under detention of women during the child-bearing period, which would diminish, and probably extinguish the supply of defectives.

#### HARVEIAN SOCIETY OF LONDON.

CLINICAL EVENING HELD AT ST. MARY'S HOSPITAL ON JANUARY 28TH, 1909.

DR. WILLIAM HILL demonstrated direct vision laryngoscopy, and tracheo-bronchoscopy. Using Brüning's or Chevalier Jackson's instruments, he showed (1) Growth on right vocal cord; (2) pachydermia of cords; (3) tuberculous growths; (4) tuberculous laryngitis, where the ulcerations had healed under daily direct vision treatment in hospital; (5) subacute laryngitis; (6) chronic laryngitis. He also demonstrated the bifurcation of the trachea. After cocainisation of the larynx, a tracheoscope was passed through the vocal cords during inspiration to a distance of 3 inches. After further cocainisation, Bruning's extension bronchoscopic tube was passed through the tracheal tube to the bifurcation. No coughing occurred in any of these cases, showing the efficiency of Mr. Harrison's method of cocainisation. Dr. Hill also showed the instruments used in œsophagoscopy, and related a case in which he had used it. He showed Chevalier Tackson's gastroscope, together with the laryngeal and tracheal instruments of Kirstein and Killian, which led up to the perfected instruments of Brüning and Jackson.

Mr. Cecil Graham exhibited by direct laryngo-scopy, the condition of a tuberculous patient from whom an interarytenoid tuberculoma had been removed unde chloroform by the aid of Brüning's laryngoscope.

Mr. FITZMAURICE-KELLY showed a case of endothelioma of the tonsil with enlargement of the cervi-cal glands; and also a case of osteo-arthritis of the left metatarso-phalangeal joint of the great toe, asso-

ciated with cystitis.

Dr. Willcox showed a case of collapsed lung with secondary fibrosis in a child. He discussed the possibility of congenital bronchiectasis and fibrosis fol-

lowing phthisis.

Mr. LAMING EVANS showed a case of congenital dislocation of the left hip of the supracotyloid variety in a girl, æt. 7. There was a complete absence of lordosis. Trendelenburg's sign was present.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD IN THE FACULTY HALL, FRIDAY, FEBRUARY 19TH, 1909.

Dr. ROBERT JARDINE in the Chair.

BEFORE proceeding with the business of the meeting, Dr. JARDINE made references to two former Presidents of the Society, namely, Dr. John Lindsay Steven and Dr. Henry Edward Clark, who had recently been

Dr. Henry Edward Clark, who had recently been removed by death.

The Society met for the purpose of holding a "Discussion on the Treatment of Suppurative Appendicitis," which was introduced by communications by Sir George T. Beatson, K.C.B., Dr. T. Kennedy Dalziel, and Dr. Donald McPhail.

Sir George T. Beatson said the discussion was

suggested to him by a case he had under his care in hospital. The patient, suffering from supputation appendicitis, was sent to hospital by a general practitioner. He returned home in three weeks quite well, without having undergone any surgical operation. The practitioner then wrote a letter to the house surgeon calling in question the treatment adopted, and making it evident that he thought it inadequate, if not quite wrong. This made it appear that the prevalent opinion in the profession was that when appendicitis assumed the suppurative form or reached the suppurative stage, it should no longer be treated otherwise than by immediate operation. Dr. Beatson not only thought differently, but his conviction was so strong that he based his practice upon it; and, in comparing results, he found the statistics justified him in doing so. The mortality in cases of suppurative appendicitis was high, and the chief reason for this was the supervention of general septic peritonitis as the result of operation when there was only a local collection of virulent pus in the region of the appendix. He maintained that the proper treatment in localised aprendicular abscess was expectant, and gave his reasons for treating the case medically but carefully for two or three weeks. The most important was that in that time the virulence of the pus and its micro-organisms has greatly diminished, and that if operation was then thought advisable, the risk of general infection of the peritoneum was very slight. Again, the appendicular abscess often ruptured into the bowel, or came to the surface and opened externally, while the adhesions prevented the pus getting into the peritoneal cavity. Waiting also allowed the process of leucocytosis to go on and inhibit the action of the micro-organisms, and prevent their spreading.

In cases where the suppuration was diffuse, early operation was called for, so that Dr. Beatson made a clear distinction between the two varieties of suppurative appendicitis, namely, the localised and the diffused. He also gave reasons for limiting the discussion to suppurative appendicitis. He then gave an illustrative case of: (1) Localised suppurative appendicitis, with its symptoms and treatment; (2) Diffuse suppurative appendicitis, with its symptoms and treatment. Then he pointed out that general peritonitis was not necessarily suppurative, and that the intensity of symptoms was no guide to the severity of local con-

The value of various diagnostic signs was ditions. explained. The treatment of each variety of suppurative appendicitis was then mentioned. Success in early operations for non-suppurative appendicitis was no reason for early operation in the suppurative variety. Even perforation and gangrene of the appendix do not of themselves justify operation; for, in his opinion, the danger of the condition becoming general as the result of operation was so great that he attributed the high mortality of suppurative appendicitis to early operative interference. The principle of opening and getting rid of any collection of pus as soon as possible was good; but in these cases he held that the practice of it was beset with greater danger than that which resulted by leaving the pus to Nature and judicious medical treatment, except in the case of diffuse suppuration, which is a very rare condition. In the localised variety pus is a bar to operation, and operation makes an anxious condition serious. Dr. Beatson prefers to keep the patient on low diet, such as albumen, water, relieve pain with opium, avoid all laxatives, but keep the intestines at rest. Enemata for constipation; boracic poultice locally. Wait till abscess points at surface, which it generally does, or escapes into the rectum, and until the pus is less virulent; then, if you think operation advisable, you can do it with greater

safety to the patient.
Dr. T. KENNEDY DALZIEL began his communication by discussing the ætiology of suppurative appendicitis. He found suppurative appendicitis frequent in certain families, and seeking for an explanation of this led him to examine many appendices other than those removed for disease. He is of opinion that, apart from typhoid fever, dysentery and cancer, a common cause of appendicitis is a stricture at the orifice of the appendix. This is a fairly common condition, and makes the appendix funnel-shaped with the orifice as the narrowest part. This prevents the escape of mucus or foreign bodies of any kind, which act as a source of irritation. A catarrh of the mucous membrane results, which makes the condition worse. This, however, is not a serious condition, unless it goes on to ulceration of the wall of the appendix and empyæma of the appendix. The danger of the localised suppurative appendicitis resulting varies with the micro-organism that is present. When it is only bacterium coli commune that is present the danger is least, it is greater when the staphylococcus danger is least, it is greater when the staphylococcus is the micro-organism, and greatest of all when it is due to streptococci. The pus was first of all inside the appendix, which was blocked with some foreign body, and had its lumen constricted; but many complications might follow upon this: as localised abscesses, adhesions, perforation and escape of pus into peritoneal cavity colon, cæcum, rectum, bladder, ureter and other organs; also thrombophlebitis of the mesenteric veins, and septicæmia without peritonitis. Sympathetic glands in the mesentery may also become infected, suppurate and in the burst, and when this occurs fatal peritonitis is the usual result. With all these complications ready to occur at any moment, Dr. Dalziel thinks the dangers of delay in evacuating the pus are very much greater than any danger resulting from skilful operative interference. He is of opinion that the best treatment of localised suppurative appendicitis is early operation, unless in cases where the operation will lead to general peritonitis. His experience is that the localised abscess may become a general suppurative peritonitis at any time, and early operation is the best means we have of avoiding this, and the other dangerous complications mentioned. The technique of the complications mentioned. The technique of the operation is the important thing, for by defending the peritoneal cavity by gauze from the area of infection it is seldom you cannot prevent general peri-toneal infection. The septic focus can be removed, and you avoid all other complications; whereas by waiting for adhesions to form, you leave something behind which may cause fresh attacks at any time. If there is no general peritonitis, Dr. Dalziel is of opinion that there is no reason for leaving a local collection of pus or a suppurating appendix, and he thinks the proper treatment is to remove it at once.
Dr. Donald McPhail's communication dealt with

peritonitis from the general practitioner's point of view. The commonest form of appendicitis was non-suppurative, and this was not a dangerous condition; his experience being that they did not prove fatal. He then dwelt upon the necessity for careful diag-nosis before deciding upon surgical interference, for if there was no suppuration there was no need for operation. If, however, it could be ascertained that pus was present, he thought it was the best treatment to get rid of it at once. Regarding the use of opium, he considered it cruelty to withhold it for pain. His practice was to give morphia along with small doses-of sulphate of magnesium, as this helped the mucous membrane of the bowel to secrete its juices and so prevent constipation and the formation of scybala. When operation was required at all, it should be thorough, and the drainage of abscess cavities should be down hill through large tubes to be really effective.

Mr. A. E. MAYLARD expressed the opinion that one's hospital experience biased their view regarding conclusions about the gravity of suppurative appendicitis, as only the worst cases were sent there. mortality among them was consequently high. He gave statistics of cases treated in the Victoria Infirmary in illustration of his opinions. He was convinced that a case of appendicitis becomes severewhen pus forms, and that the risks run while it is. present are so great that a radical operation is certainly to be preferred to waiting. There was certainly danger in operation where the pus was localised and there was no general peritonitis; but with care and with the dangers that attended the presence of pus-

in the appendix.

Dr. JAMES C. RENTON remarked that without doubt the virulence of the pus in suppurative appendicitis: was dependent on the kind of micro-organism present in it; yet they could not tell what the nature of the micro-organism was until they had examined the pusfor it. He therefore considered that the sooner a local collection of pus was opened the better. That was the important thing in all cases. Then the appendix could be removed during the same opera-tion, or in many cases he would wait for a week or a few days before taking the diseased appendix away. His experience of general peritonitis from perforation was most severe when due to streptococci, and least so when the bacterium coli commune was the cause.

Dr. JAMES H. PRINGLE expressed the opinion that pus should be evacuated at once, and would make no exception to this rule. He could see no harm in removing the appendix early, nor any advantage in leaving it to be dealt with at another operation. Hementioned the importance of early operation in diminishing the duration of the illness; and considered that for this reason pus should be removed at the earliest possible time. This gave the patient the advantage of a shorter period of acute illness and earlier convalescence. His experience was that apppendicular abscess frequently ruptured into the peritoneum or bowel if not operated upon in time. In the treatment he avoided the use of opium.

Dr. DAVID N. KNOX was of opinion that the expectant treatment in suppurative appendicitis was not good surgery. He adhered to the view that early operation was the best treatment, and he always gave opium

for pain.

In reply to a few questions, Dr. DONALD MCPHAIL stated that no hard-and-fast rules could be laid down to be followed in every case, but that the principle of removing pus when present was certainly to be acted upon when possible.

Dr. T. KENNEDY DALZIEL thought the consensus of opinion was in favour of the views expressed by him regarding the removal of pus as soon as possible. Regarding opium, he would give it for the relief of pain, but not in quantities sufficient to narcotise the patient.

Sir George T. Beatson brought the discussion to a close by re-stating his opinion that early operation was the greatest risk a patient with suppurative appendicitis could run, that there should be no surgical interference till the condition had quieted down, and the

virulence of the pus diminished, which it usually did in two or three weeks' time.

#### LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD ON THURSDAY, FEBRUARY 11TH, 1909.

The President, Mr. T. H. BICKERTON, in the Chair.

Dr. W. B. Warrington described a case of myasthenia gravis in a woman, æt. 32. The ptosis often so readily seen, was not marked, though it could be produced to some extent by fatigue. There was extreme weakness of the masseters, which gave the characteristics. racteristic myasthenic electric reactions. ways the case was quite typical. In other

Dr. GLYNN referred to a case which commenced with giddiness, double vision, and ptosis, the latter being transitory. There was considerable loss of voluntary muscular power of the legs after exercise or excitement, and death occurred in twelve months from bulbar symptoms, these develop-

ing and proving fatal in four days.

Drs. Murray Bligh and Ernest Glynn read a note on the diagnosis of typhoid fever by bacteriological examination. Their method was based on lines suggested by Coleman and Buxton, of New York, particularly in the employment of sterilised ox bile medium. In eight out of fifteen cases of typhoid examined in the second and third week they obtained positive results. The method proved of distinct value in two cases in which the nature of the disease was obscure.

Mr. MONSARRAT read a paper on cancer of the breast. He discussed the difficulties of early diagnosis. He described the extent of the operation undertaken in 37 cases, and their after histories. There was no recurrence in twenty cases during a period extending from five years to one year. Recurrence had taken place in fourteen cases during periods ranging from

four years to within one year.

Mr. PAUL referred to the importance of removing breasts affected with intractable involution mastitis before they become malignant, and the great value of rapid sections. He thought the modern operation gave decidedly improved results. Mortality from the operation was very low. He had removed the breast over 200 times during the last five years without a death, and had no death since year. In thirty work death, and had no death since 1901. In thirty years he had had only four deaths from breast operations two from sepsis and two from acute mania.

#### CORRESPONDENCE.

#### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE, Paris, Feb. 21st, 1909,

AEROPHAGIA is a gastric symptom known for a long time, but its semeiology has been only recently studied. It is characterised by abundant and frequent eructations observed in dyspeptic and neurotic persons.

The gas expelled at the time of these eructations,

and with which the stomach is charged, can either be produced by gastric fermentation, as in the case of dyspepsia, or may be derived from air unconsciously swallowed by neurotic persons. It is to this deglutition, followed by more or less abundant eructations, that the name of aerophagia should be reserved.

The gas accumulated in the stomach provokes distension and flatulence, and exercises a certain compression on the neighbouring organs-sensation of oppression, palpitations, irregularity in the cardiac rhythm,

tympanitis, general lassitude.

These phenomena become still more exaggerated at the moment when eructation is about to take place. Patients frequently suffer at this point from vertigo. dizziness, with a tendency to fainting.

But when eructation sets in-which the patient tries to provoke by swallowing a new dose of air, so as to establish the equilibrium between the exterior pressure and that of the gastric gas-a feeling of immediate relief and bien-être supervenes.

The patient frequently ignores the special nature of this tic of gaseous deglutition; the medical attendant whose attention is not drawn to the fact sometimes neglects to examine the nervous condition of the patient, and ascribes to gastric fermentations the eructations from which he suffers.

However, in these cases the digestive functions, although not absolutely perfect, are not troubled to the point of causing such accentuated fermentations.

Anyhow, the anti-putrid treatment—charcoal, gastric

antiseptics, alimentary regime—have no effect on the troubles of the patient. The exact origin is only discovered by attentively examining the patient. Before eructation he fills his mouth with a certain quantity of air, which he sends down to his stomach by hermetically closing his mouth, bending his chin towards his chest, and making a motion of deglutition with a slight noise due to the raising and descent of the pharvnx.

The air expelled is absolutely inodorous, and is thus distinguished from the putrid gases of gastric fermentation.

According to Dr. Lyon, aerophagia sometimes takes the form of a convulsive attack, and the patient feels it coming on like an attack of epilepsy. Preceded by dizziness, noises in the ears, vertigo, general uneasiness, the phenomenon sets in; the patient is obliged to stand, and for a variable length of time emits sonorous eructations in rapid succession, when the attack ceases, leaving him in a state of complete lassitude.

Mental examination of these patients confirms the diagnosis. The majority are, if not hysterical in the true sense, hyper-nervous; they are certain that they are suffering from acute gastritis, grave dyspepsia, cancer of the stomach, etc. They refuse to eat for fear of increasing their suffering, and thus their general condition suffers from insufficient alimenta-

The diagnosis of this affection is not very difficult, as the attention of the medical attendant is drawn by the patient himself to the eructations, and it is for him to discover their origin. The almost negative examination of the stomach--palpation and percussion reveal nothing abnormal, the absence of odour in the gas rendered, the interrogation of the patient as to his nervous and mental condition, should put him rapidly on the track.

The treatment of aerophagia should be addressed to the cause—suppression of deglutition of air. This is difficult, as the patient will refuse to believe that his ailment is of purely nervous origin, and will insist

So as to accord to a certain extent with his ideas, non-alkaline digestive agents will be prescribed, notably ferments, and the patient will be persuaded that he will completely prevent eructation by stimulating the certain function. lating the gastric function.

But at the same time he will be recommended to make no effort at deglutition outside his meals, and to place a piece of cork between his teeth at the end of the repast, for deglutition of air is impossible with the mouth open.

HEMOPTYSIS AND HEMATEMESIS.

It is sometimes impossible, when in presence of a patient who vomits blood, to know at once if the hæmorrhage is of gastric origin or if it comes from the lungs; if it is hæmatemesis or hæmoptysis. If, however, the question is of primary importance in the ulterior treatment of the affection that produced it, it occupies a second place as regards immediate treatment. For the moment the essential point is to arrest the hæmorrhage, says Prof. Huchard, regardless of its origin, and this is generally obtained by temporary suppression of food, rest, complete silence, one or two injections of morphia, and, in the case of hæmophilia, injections of anti-

diphtheritic serum.

The days following the initial cause becomes more or less apparent through information obtained from the family of the patient and a careful examination, eliminating lesions of the nose, mouth and pharynx.

According to the information received and personal observation, different affections might be incriminated.
Ulcer of the stomach, if the patient suffered from industrian sensation of burning, and acute pain in

the epigastrium.

Hepatic affection (cirrhosis or tumour) producing small varicose veins in the esophagus or of the stomach, if the complexion wore an interic tint.

Pulmonary tuberculosis, if the vomiting of blood has been preceded by wasting, cough, night sweats. Mitral disease, if the congestive lesions observed in the lungs yield to the administration of dilatation. Infarctus, if a bruit de valor is heard in the heart on Infarctus, if a bruit de galop is heard in the heart on the patient walking rapidly for a few moments.

Cancer of the stomach is revealed by the cachectic

condition of the patient.

Aneurysm of the aorta is difficult to recognise, and

frequently radiography has to be resorted to.

Hæmorrhage has been observed in certain general maladies, as grave icterus, scurvy, leukæmia, infectious endocarditis, auto-intoxication of renal origin, and such local lesions as ulcers of the duodenum, alcoholic gastritis, hydatid cysts of the lung, pulmonary syphilis or poisoning by injection of caustic substances substances.

The exciting cause of hæmorrhage discovered and the question of hæmoptysis or hæmatemesis settled; the way is opened for the treatment.

In hæmoptysis the suppression of food need not generally exceed 24 hours; in hæmatemesis it should be prolonged three or four days and even longer, the patient being nourished by enemas. In hæmoptysis where hypertension generally exists, hypotensors as inhalation of nitrite of amyl, trinitrin, mistletoe give encouraging results. Ergotin, chloride of calcium,

or both alternately, may be tried.

Hæmatemesis should be treated by subnitrate of bismuth and bicarbonate of soda. Surgery comes in only where the hæmorrhage persists in spite of all

other treatment.

The resulting anæmia should be treated with physiological iron as afforded by hæmoglobin, which is easily assimilated and produces no accidents.

#### GERMANY.

Berlin, Feb. 215t, 1909.

At the Verein für Innere Medizin, Hr. Strubel spoke on

VACCINE TREATMENT. He said that, with regard to all therapeutical measures, it was necessary that they could be easily carried out by the practitioner. It was not a simple procedure that had been given to the world by Almroth E. Wright—the determination of the opsonic index and the vaccine treatment depending on it-but a very complicated method. In London as well they had not been able to determine the index as often as could be desired, and a modified method had been made use of. speaker had attempted to simplify the process; he had determined the index for some length of time in cases of tuberculosis, and had then applied the vaccine treatment without again having recourse to a fresh index, and with very good results. The like took place with regard to staphylococcus diseases; they also were successfully treated by vaccine without determination of the index. He had now had the vaccines prepared in the factory, and had made use of them in 40 cases successfully, and without setting up any reaction. In cases of chronic acne a longer time was, of course, necessary (several months) to bring about the result that was desired. The vaccines had been prepared in the was desired. Ine vaccines had been prepared in the Güstrow chemical works, and they would shortly be on the market under the name of "opsonogen"; I commontained no millions of staphylococci. An ordinary furuncle had already been cured by two injections. In order to prevent relapses a lengthened series of injections should be made twice a week. From the speaker's own experience he should say that there was not the slightest objection in placing "opsonogen" in the hands of the general practitioner. Wright had also recommended a similar procedure in the Practitioner.

Hr. Rosenheim next related a case of Wright had also

ACTINOMYCOSIS IN CARCINOMA OF SIGMOID FLEXURE. A gentleman, æt. 61, who had always been otherwise

healthy, complained that for a year he had suffered from constipation, but that latterly he had had attacks of abdominal pain with vomiting and diarrhæa, which, however, always passed off quickly of themselves. In nowever, always passed off quickly of themselves. In the autumn of last year he experienced a feeling of pressure over the bladder, and pain in the left inguinal region. Nothing special could be felt on palpating the abdomen. A later examination, however, showed a considerable collection of fæces in the neighbourhood of the sigmoid flexure. An endoscopic examination showed a growth that blad engilly covered with macous showed a growth that bled easily, covered with mucous membrane, in which were large vessels. An examina-tion made a few weeks later revealed the following: The tumour was unchanged on the left, but on the right there was a deposit some centimetres square, greyish-brown and slimy, like necrotic tissue. From this carcinoma of the sigmoid flexure was decided on. The masses that appeared to be necrotic proved to be harmless, only slightly changed mucous membrane. In the mucous membrane over the tumour, actinomycoses were found, but no intestinal mycosis was diagnosed during life. The case showed that such fungi could develop anærobically. The troubles were caused by the development of the stricture; the intection caused no symptoms. The mycotic covering had a thickness of 2 mm.

In view of Workmen's Compensation Acts, the relationship of certain diseases to accident becomes one of importance. Two such cases are quoted in the Deutsche Med. Zeit., February 11th, 1909, communi-

cated by Dr. H. Strohe, Köln.

Both the patients were young men who had been healthy up to the time of the accident, and both fell neating up to the time of the accident, and both fell from a considerable height. One complained of pain in the inguinal region, which ceased, but returned with fever on attempting to stand, and which gradually became more and more fixed in the region of the cæcum. An operation was performed six months later. A band was found, like a tight ligature, round the extremity of the vermiform appendix, which was in an almost gangrenous condition. In the other case the patient complained from the first of pains in the inguinal region and back; the first-named pain disappeared, but that in the back remained. The abappeared, but that in the back remained. The ab-dominal pain soon returned, however. Laparotomy was performed three months after the accident. A very long vermiform process was found, the extremity of which was fixed to the lumbar vertebræ. On separating the adhesion the serous covering of the distal end was left behind. During the course of a few weeks an abscess formed at this spot, which pointed towards the

middle line of the abdomen, and was there opened.

In both cases the writer believed there was a causal connection between the accident and the appendix mischief, that in the first case the disease was produced by a contusion of the abdominal wall; in the other case the unusually long processus had become attached to the contused lumbar vertebræ, the contusion being

caused by the fall.

## AUSTRIA. Vionna, Peb. 21st. 1909.

TRACHEAL STENOSIS AND OSTEOPLASIA. Moszkowicz presented a female patient to the members of the Gesellschaft der Aerzie on whom he had successfully operated for stenosis in the trachea.

The patient was 37 years of age, with a defect from infancy that threatened to prove fatal. After much thought and consultation he decided to operate after Schimmelbusch's method to relieve the woman's distress. He found later that he would have to modify the operation, and divided the description into three parts:—(1) The mobilising and distending of the trachea according to Küster; (2) the covering of the various parts with periosteal tissue from the sternum and the clavicle, after Schimmelbusch's method; and (3) the covering of perichondrium in the cartilaginous regions. SYRINGOMYELIA.

Schlesinger presented a woman who had twice been confined, and on both occasions had no pain, or rather did not experience pain, neither could she tell when any movement took place in the abdomen. This peculiar condition depended on the special or specific

as Schlesinger wishes to call it, supply of the sympathetic in the peritoneum, and walls of the uterus being quite lost, or that no communication existed between these and the spinal cord. This specific sensation of the uterus can be quite destroyed without any obvious loss to any other textile position of the abdomen, as the centre of the cord is not the only path for transmitting these sensations, but it is diffused throughout the white substances. It should be noticed that uterine sensations would enter the cord in the sacral region, which render them subject to interruption in passing to the cerebrum. Proof of this specific uterine pain can be demonstrated by dividing or partially dividing the posterior horn of the spinal cord. Latzko remarked that the uterine pains, sensations of the outer surface of the uterus and sensations of the inner surface of the uterus were not conducted by the same path. He admitted, however, that the movement of the child under normal conditions was conveyed by the apparatus that transmitted the internal surface of the uterus, although it was possible, and experiments sometimes tended to prove that the peritoneal surface was also transmitted through the same channel. Schlesinger said that the peritoneum was more frequently free from pain than in any other condition of syringomyelia. He re-corded a case of perforation where severe peritonitis was present, but the patient was quite free from pain to the last.

MYOGENIC CONTRACTION.

Erben exhibited a three-year-old child, who, having recovered from a broken arm, had all the symptoms of myogenic contraction. During the treatment the fingers assumed a claw-like appearance under the bandages. There was no lesion of the nerves, while the phalanges when stretched out contracted firmly, indicating that the conducting power of the nervus radialis was intact. There was no atrophy in the muscles of the hand or in the fingers, which usually occurs in peripheral paralysis. He considered the cause to be one of a fibrous inflammatory retraction, or possibly an ischæmic condition of the muscles. Moskowicz was of opinion that the contraction was due to ischæmia, which was not infrequently the case in fractures of the lower third of the humerus. This lesion was usually attributed to a tearing of the arteria cubitalis, probably producing a hæmatoma that may prevent the easy formation of collateral circulation, and thus affect the whole group of muscles in the forearm by damaging the circulation. It is possible that a necrosis and degeneration of the fibrous tissue may be induced, but it is purely of a myogenic nature, and never under any circumstances akin to a neurogenic contraction.

#### LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

#### OXYGEN IN SPORT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—In your issue of February 17th a paragraph appeared on "Oxygen in Sport," in which the experiments of Dr. Leonard Hill on athletes, and his lecture at the London Institution, are commented upon. Dr. Hill, it would appear, has found that 'oxygen has a wonderful effect on athletes." He has shown that a draught of this gas when a boxer was winded had the power of restoring him wonderfully and increasing his staying capacity. The same thing was observed in hockey and football players. This, you say in your annotation. "may be good physiology, but it is bad sport." With regard to the question of sport, that is, of course, a matter of opinion. The subject has, however, been so thoroughly thrashed out of late in the columns of the daily and weekly Press that it is un-necessary to discuss this point further. With refer-ence to the physiology of the inhalation of oxygen in sport, I would call your attention to the fact that the very elementary observations made by Dr. Hill, the conclusions of which, based entirely upon the statements of his subjects, are totally wanting in

physiological control, were anticipated by me seventeen years ago. At that time I contributed an article on the physiological action of cycling to La Semaine Médicale. I made also a series of experiments, which were fully reported at the time, and are well-known to all sportsmen and athletes in France. I devised different forms of apparatus for the administration of oxygen, not only before and after, but during actual effort. I took sphygmographic tracings of the pulse at the moment of extreme loss of wind, which showed the almost total absence of tension in the left heart, resulting from the difficult circulation of blood through the lungs; also after the inhalation of oxygen, which restored wind at once by rendering the lung adequate to the extraordinary demand on it, thus enabling the blood to pass freely into the left ventricle, and so restoring tension. The apparatus I devised was tried by many cyclists, and would doubtless have come into general use but for the objection of sporting authorities.

I forward herewith a copy of a pamphlet in which the subject is more fully discussed, and you will find in it the text of the articles published by me in 1892, with the pulse tracings above alluded to, as well as others of a sporting interest. I do not pretend to have been the first in this field, for it is quite possible that others may have preceded me. My experiments, how-ever, show once more that there is "nil novi sub sole."

I am, Sir, yours truly, ary 19th, 1909. OSCAR JENNINGS. Paris, February 19th, 1909.

THE CENTRAL MIDWIVES BOARD AND SEPSIS. To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your correspondent in the last week's issue, who styled himself "Pathologist," appeared to be startled at the indifference of the Central Midwives Board to the dangers of puerperal sepsis, and then stated that, contrary to all modern teaching it directs candidates preparing for examination to make during labour "repeated abdominal and vaginal examinations." Now, by reference to the Rules framed by the Board, the writer of this letter will be able to discover that these words occur in the certificate which must be produced to prove that the candidate has undergone the required course of practical training under a registered medical practitioner or a certified midwife appointed by the Board, and that she has also attended and watched the progress of not less than twenty labours, and, under personal direction, that she has had the opportunity of obtaining by internal and external examinations a practical knowledge which can be secured in this way without any risk to the patients.

I hope this explanation will be satisfactory to "Pathologist," and that he will be comforted by the assurance that the Central Midwives Board is quite as anxious as he appears to be to stamp out puerperal sepsis, and to protect the poor women of our country against ignorance and preventable disease.

I am, Sir, yours truly,

JOHN WARD COUSINS.

Portsmouth, February 22nd, 1909.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. Sir,—Heaven forbid that I should undertake the task of offering an apologia for the actions of the Central Midwives Board, because too many of the actions of that body are incapable of defence. I think, however, that in the present instance "Pathologist" is a little too hard upon it. He is quite right in thinking that modern obstetrics teaches the necessity of avoiding vaginal examinations as much as possible; but, at the same time, it recognises that one such examination is necessary in every case, if for no other purpose than to exclude the possibility of the presence of pathological conditions of the vagina. To make this examination with satisfactory reults, the nurse must acquire experience, and how can she do this unless she makes "repeated vaginal examinations" during her training? It is surely far better tions" during her training? It is surely far better that she should make them then, when presumably she is under proper control and supervision, instead of after her traume, irresponsible position.

I am, Sir, yours truly,

OBSTETRICIAN. of after her training, when she is in a comparatively

RUNNING FOR BOYS.

10 the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—It seems to be the fashion nowadays for groups of medical men who happen to hold strong views on any point to publish manifestoes for the instruction of the public. Thus, a year or two ago, we had the "Alcohol" and the "Anti-Alcohol" manifestoes, and now we have Sir Lauder Brunton and his friends declaring ex cathedra against long-distance running for boys. Views expressed in this manner do not usually carry much weight with the profession, but with the public there is a danger that they may be regarded as expressing received medical opinion. As a matter of fact, is there any evidence that, on the whole, running is bad for growing boys? I know of none, but, on the contrary, there is plenty of evidence that the boys and young men who have been distinguished as athletes in school and college life are longlived and healthy. Their lives are, in fact, in insurance phraseology, "first-class." Examination of the lives both of old "Blues" in this country and of men of similar distinction in America has quite contradicted the tradition of high mortality among athletes. It is not, of course, to be denied that running may be of injury to an occasional boy, but, on the whole, long-distance running tends to reject the unfit early, and without much injury to themselves. There is no doubt that it develops certain admirable qualities—perseverance, courage, determination—which the onlooker at a football or cricket match may admire in others but has little chance of cultivating for him-The schoolboy will either look on or take part letics. Those who love manliness prefer to see in athletics. him do the latter.

I am not an ardent admirer of the recent developments of the "Marathon" craze, but, at any rate, experience has shown that the tests, severe as they are, are not followed by any permanent injury to the competitors.

I am, Sir, yours truly,
OLD RUNNER.

#### OBITUARY.

DR. LINDSAY STEVEN.

THE sickle of death has been busy lately among the distinguished medical men of Glasgow. We have now to chronicle the death of Dr. John Lindsay Steven, in his 51st year, which took place at his residence rather suddenly on February 14th, 1900. It was not known that he had an affection of the kidneys for the last two years, and his death seems to have been precipitated by an acute attack of nephritis, complicated with pericardial effusion. Dr. Steven was in the full zenith of his powers, and his services as a reliable consulting physician were much in demand. For nearly thirty years he had worked and prepared himself for high professional distinction, and was about to er joy the full fruits of his strenuous and honest career when he was called to his rest.

Dr. Steven was a graduate of the University of Glasgow, receiving his M.B., C.M., with honours, and winning the Brunton Memorial Prize as the most distinguished graduate of his year. After a sojourn on the Continent, he was appointed pathological assistant to the late Joseph Coats, a name still revered for his work in pathology in Glasgow. Dr. Steven spent many years with Coats, and was of great assistance in helping students in acquiring a sound pathological training. He, early in his career, published a small handbook on practical pathology, which was distinguished for its lucidity, and was a reflex of the Glasgow teaching. About this time he likewise was a clinical assistant to the late Professor McCall Anderson, a man distinguished for his energy and fertility of resource in the therapeutics of disease. When Dr. David Newman retired from the lectureship of pathology at the Glasgow Royal Infirmary, he was succeeded by Lindsay Steven, who proved himself an expert pathologist, and one who could advance the science by his splendid gifts. It is, perhaps, to be regretted that Dr. Steven chose in the later part of his career to pursue clinical medicine and to renounce his purely pathological work, as it must be known,

judging from the character of it, that he would sooner judging from the character of it, that he would sooner or later have attained what was perhaps the great ambition of his life, namely, professorial rank. At the time Coats died, Steven had become a physician to the Royal Infirmary, and had hived off from pathology, so that when Professor Muir got Coats' chair, Steven's chances were handicapped. About three years ago, when James Finlayson died, Steven was unanimously chosen as his successor in the Western Infirmary, an appointment that met with the hearty approval of the medical profession in the West of Scotland. Had he been spared long enough, he of Scotland. Had he been spared long enough, he would, in all probability, have risen to professorial rank in medicine.

Dr. Steven was a man of a calm and reflective type of mind, who took life seriously and earnestly, and was actuated by the highest Christian ideals. He worked steadily and conscientiously, and any success he attained seemed to be the logical result of the work done. He employed no arts to attract practice; he sought no notoriety by any eccentric habits of mind; and he was deeply respected by students and practitioners, for he never seemed desirous to enhance his fame by taking advantage of the mistakes or omissions on the part of the family attendant. He made a thorough examination of the patient, and stated his opinion honestly and as charitably as circumstances permitted.

Dr. Steven's most important contributions to medi-Dr. Steven's most important contributions to medicine are: on the "Suppurative Diseases of the Kidneys"; on "Mediastinal Tumours"—a work of European reputation; on "Fibroid Diseases of the Heart"; on the "Coronary Arteries," and many other subjects. His clinical contributions, while marked by accuracy of observation, were not so profound as his pathalogical contributions.

found as his pathological contributions.

Dr. Steven received during his life time many marks of regard from his professional brethren. He was Honorary Librarian to the Faculty of Physicians and Surgeons, Glasgow; a past-President of the Medico-Chirurgical Society, and also a member of the General Medical Council. In all matters affecting the welfare of his professional brothers have been been sometimed. of his professional brethren he took a leading part, and at medical meetings he was a faithful attender. and what he had to say was to the point and in-structive. Dr. Steven had been married a few years, and much sympathy is felt for his widow in her sudden bereavement.

### EMERITUS PROFESSOR D. J. HAMILTON, M.B.,. LL.D.Ed., F.R.S.

WE regret to have to announce the death of Professor Hamilton, which took place at his residence on February 19th. Professor Hamilton had been in failing health for about a year, and resigned his chair in the University of Aberdeen last autumn, on account of his inability to attend to its duties. Professor Hamilton was a native of Falkirk, and graduated in Edinburgh in 1866. He studied pathology in Vienna, Munich, Strasburg, and Paris, and on his return to Edinburgh was appointed assistant to the late Professor Sanders, then Professor of Pathology, and was also appointed Pathologist to the Royal Infirmary. As a teacher and demonstrator of pathology he was extraordinarily successful. All his old pupils are agreed that his instruction was unsurpassable in its lucidity and in-terest. On account of the state of Professor Sanders' health, a great deal of the work of the chair devolved upon Dr. Hamilton, and when the professorship fell vacant it was a keen disappointment to very many of Hamilton's friends and pupils that he was not selected to succeed Sanders. In 1882, however, he was elected to the chair in Aberdeen, and it is safe to say that no one has ever shed greater lustre on the northernmost of our Universities. Dr. Hamilton's work on pathology is too well-known to require reference. He wrote a deservedly admired text-book on the subject, and made many important researches, among which those on tuberculosis, on the topography of the brain, and on "braxy" in sheep may be mentioned. He was a musician, and an artist of no little merit; the collection of painted casts and models in the museum of Aber-deen University bear testimony to his skill with the

#### THE ROYAL COLLEGE OF SURGEONS IN IRELAND -ANNUAL DINNER.

THE annual dinner of the Royal College of Surgeons in Ireland was held on Saturday, Feb. 20th, and was very largely attended. His Excellency the Lord Lieutenant was present, and a large party of the Viceregal Household. Before dinner there was a pleasing ceremony at which the President of the College presented Professor Alec Fraser, Professor of Anatomy in the College School, with a casket containing a cheque, in token of the manner in which the Council of the College appreciated his services to the school to which he had been attached for 25 years. After dinner the health of Professor Fraser was included amongst the toasts. Dinner was excellently served and at its conclusion and after the King's health had been drunk, the President, in proposing the health of the Lord Lieutenant, said: As they were aware, the Royal College of Surgeons was at present engaged in a struggle for what they considered their rights. (Hear, hear.) They were striving to obtain from the Government their due share of the endowments which were at present being distributed for educational purposes so largely in this country. That was not the moment for airing their grievances, but he would like to lay it down that they did not abate one tittle of their demands—(hear, hear)—and he would like that any words of his that night would be taken—as the lawyers said—without prejudice as regarded their claims. He was convinced his Excellency sympathised with them and was their friend, and would like to assist them in every way he could. (Applause.)

His Excellency, in the course of his reply, said that he would try to adopt the same method as that which had been followed by the President, namely, in clearing the ground in regard to a most important matter, as to which he made a discreet but very clear and definite reference. To have omitted allusion to a subject in which the Royal College of Surgeons naturally feels such a profound interest, would not have imparted a sense of reality to our proceedings; while, at the same time, as the President evidently recognised, it is not exactly the occasion for anything of the nature of a discussion. He would only say that the sentiments of good-will which have just been attributed to himself do exist, and glad indeed would he be if he could say more, but, as they were no doubt aware, the administration of public funds is not one of the matters which are, in any direct manner, allotted to the Lord Lieutenant, his share in such being only of a collateral sort, or perhaps even less than that expression would imply. However, the

subject is, at any rate, still under consideration.

Dr. R. H. Woods, the Vice-President, then proposed the toast of "The Guests," and this toast was responded to by Mr. Justice Kenny, the Provost of Trinity College, and the Rev. T. A. Finlay, S.J. The President next gave the health of Professor

Alexander Fraser, on the occasion of his 25th year of work as Professor of Anatomy in the Royal College of Surgeons. (Applause.) They had seen him (the President) just before the dinner present Professor Fraser with a testimonial in the form of a silver casket containing a cheque, and he told him at the time that this presentation was unprecedented. It was unprecedented in his time, and he had never known the like to have occurred before, but the College of Surgeons thought the occasion was worthy the creation of a precedent. Never had the College been better served than by Professor Fraser. (Applause.) The position of Professor of Anatomy was far and away the most important in any school of surgery or medicine. The study of anatomy was the base on which all knowledge was founded. Professor Fraser had been an exceptional Professor of Anatomy. (Applause.) The presentation was made as a testimony to the incessant and untiring industry of Professor Fraser in the management of the splendid anatomical school which he had always placed at the disposal of every student of the College.

Professor Fraser, in reply, mentioned that there was not one there that night who was a member of the Council when he first made his acquaintance with it, save Sir Charles Cameron. As to the anatomical de-partment of the school, the audience would be some-what astonished to learn that it did not make a bad second to that great institution, Trinity College. (Applause.) The anatomical returns for the past 25 years when counted up were roughly 4,570 for Trinity College, 3,730 for the Royal College of Surgeons, and 3,230 for the Cecilia Street school—a proportion of 15 for Trinity, 12 for the College of Surgeons, and 10 for Cecilia Street. That was not a bad record for the anatomical department of the Royal College of Surgeons, which had always been more or less selfsupporting.

The Lord Lieutenant proposed the last toast, that of "The Royal College of Surgeons." His Excellency said that any words spoken in connection with this toast must necessarily be those of congratulation. The College of Surgeons was an institution that had done magnificent work for the country. (Applause.)
The toast having been duly honoured,

The President, in responding, said he might put the case for the College in two or three words. There were at present in Ireland six medical schools. There was Trinity College, which was richly endowed since the reign of Queen Elizabeth. There was the new National University College, and there were the Queen's Colleges of Cork, Belfast and Galway, and there was the school of the Royal College of Surgeons. Trinity College, as he had said, was well endowed, and the other four Colleges were in receipt of annual grants from the Government, which had been largely increased by the Universities Act. The College of Surgeons, however, did not get any grant. Although it did its work as well as any and better than many of them; but it got no support of any kind whatever. It had to depend absolutely and entirely on the results of its own work and on the fees from the students. That and the fact that medical education had of recent years become a very expensive thing, and therefore could not be carried on as a commercial success were the salient points in their case. It was, he thought, a further recommendation in their favour that their institutions, their schools, and their collegewere non-political and non-sectarian institutions He thought they might believe and hope that the Government would see in time that they should be placed on a level with other schools in Ireland to enable them to carry on their work. Unless some assistance came sooner or later that college must succumb to the State-aided assistance given to other colleges and schools by the Government. They hoped the Government would see their way to grant them equal treatment in this direction. (Hear, hear.)

#### REVIEWS OF BOOKS.

NALL AND LONGRIDGE'S AIDS TO OBSTETRICS. (a)

STUDENTS of medicine and pupil midwives preparing for the "orals" of the ordinary qualifying examinations, and desiring to memorise what they had already learnt from text-books and at lectures on obstetrics, would find the latest edition of "Aids" of very great service.

Longridge, with the experience of a teacher and examiner, has revised the work and brought it well up to date in every respect. He tells the student, in as few words as possible, everything he should know to satisfy an examiner at the orals, from whom, of straightforward questions are expected. No course, straightforward questions are expected. chapter can be said to possess any special merit raising it above another, the same level of excellence being maintained throughout. All the essentials of mid-wifery, and these alone, are dealt with; no space is taken up by debatable points. Students are expected to be familiar with every subject recalled to their minds by this synopsis. The book is well got-up.

(a) "Aids to Obstetrics." By Samuel Nall, B.A., M.R.Cantab. M.R.C.P.Lond. Revised by C. J. Nepsan Longridge, M.D.Vict., F.R.C.S.Eng., M.R.C.P.Lond. Seventh Edition. London: Bailliere. Tiodali and Cox. 1908.

### SUMMARY OF RECENT MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

Observations on Injuries of the Neck of the Femur in Early Life.—Whitman (Med. Record, January 2nd, 1909) states that it is generally assumed that all fractures of the hip in early life are epiphyseal separations. Of 84 cases collected from the literature by Hoffa in 1903, 80 were called epiphyseal fracture, and 4 reported by the author, fracture of the neck. During the first ten years of life at least, epiphyseal separation is unusual because the junction is protected by a firm enclosing covering of cartilage, reinforced by periosteal tissue. In adolescence the junction between head and neck becomes relatively weak. The differential diagnosis between the two conditions is important as regards treatment. Injury to the hip in a healthy person resulting in immediate disability and presenting the physical signs of fracture, whether in childhood or adolescence, is far more likely to be fracture of the neck than at the epiphyseal junction. If, on the other hand, the subject is an adolescent, particularly of the weak, rapidly growing or overweighted type; if the symptoms were induced by comparatively slight injury; if the debility was not complete, but slowly progressive, the probability is that the lesion is an epiphyseal fracture. If the separation is immediate and complete, the injury is usually more severe, and the disability is correspondingly greater. The final results of untreated cases of fracture of the neck are distorsion and apparent shortening of the limb, but comparative freedom of motion in directions not opposed by the deformity, the limitation of motion being especially the loss of the power of abduction due to coxa vara. In epiphyseal displacement there is, in addition, great limitation of motion, or partial ankylosis resulting from disorganization. sation of the joint, with a certain degree of shortening due to loss of growth. In fracture of the neck, if the case is seen early, the limb should, under traction and by carefully applied force, be placed and fixed in complete abduction for the purpose of reducing deformity. If repair has taken place, a sufficient wedge of bone should be removed from the base of the great trochanter to restore the angle of the neck and thus the range of abduction which is dependent on it. In rare cases epiphyseal separation may be complete, so that a disengagement and replacement of the fragments by manipulation may be possible, but usually the fragments are firmly adherent to one another and reposition is impossible without open operation. In these cases the anterior surface of the joint is exposed, and the capsule is opened by a straight incision in the line of the neck. The removal of a thin section of bone from the neck is often necessary to permit the insertion of a chisel with which the fragments must be prised apart to permit replacement by abduction and inward rotation of the shaft. The author outlines 15 cases to illustrate four types of fracture of the neck of the femur in early life as they are likely to be presented for treatment. (1) The unusual cases in which a correct diagnosis permits immediate correction of deformity by manipulation. (2) Cases in which the fracture has consolidated, the deformity being of a coxa vara type, which may be corrected by cuneiform osteotomy of the shaft without disturbing the joint. (3) Ununited fractures which require direct operation for the purpose of fixing the fragments. (4) Epiphyseal fractures, in which the joint must be opened.

Contusion of the Lung without External Injuries.—Payne (Brit. Med. Journ., January 16th, 1909) reports the following case:—A labourer, who up to the time of his accident felt in perfect health, while at work fell over a beam on to his right side. Not feeling very seriously hurt at the time, he continued work for two

hours and then went home. By this time the pain in his side was so bad that he went straight to bed. There he remained, and gradually got worse. On the author being called in to see him the third day after the accident, the patient was found to have marked dyspnœa. There was no sign of external injury to the chest, except redness and tenderness on pressure over a region towards the base of the right lung, where the patient complained of internal pain. There was marked dulness on percussion in this region. The general impression was a man in the second stage of pneumonia; the immediate danger was cardiac failure. The patient died a few hours later, exactly 71 hours after the accident. At the autopsy, there were found no signs of injury to the thoracic wall, no ribs were fractured, there was no laceration of the soft tissues. Extending inwards, from the surface of the lower lobe of the right lung, was a patch of red hepatisation about the size of the palm of the hand, and about 11 in thick. It was judged that this patch in situ would just correspond with the spot where the pain was so acute, and where the patient received the blow in falling. The author considered that the man died of pneumonia, secondary to contusion of the lung, contracted by the accident. He tried a series of experiments with a metal and wooden ring and weights, which tend to prove that if the ribs are fractured the danger to the lung may be less.

Bacteria of Puerperal Uterus.-Lea and Sidebotham (Journ. Obst. and Gyn., XV., 1).—The primary object of this investigation was to test the conclusions of those observers who maintain that the presence of hæmolytic streptococci in the vaginal or uterine secretion after delivery must be regarded as pathognomonic of the existence of infection. The results show that hæmolytic streptococci may exist in the lochial secretion without any evidence of infection. In a series of 58 cases in which the lochial secretion was examined between the second and ninth day after delivery. organisms were found to exist in the cervical canal and cavity of the uterus in 80 per cent. of observations. The organisms were mainly those which have been shown to exist in the vaginal secretion during pregnancy. Streptococci were present in 12 cases in all, 20 per cent. of the total number. In 7 instances the organisms showed no hæmolytic power, and corresponded in type to the streptococcus mitior of Schottmüller, or the S. gracilis of others. In all of these cases the puerperium was normal, except in one in-stance the temperature rose to 101.6° a few hours after the intra-uterine culture was obtained, and this is probably to be regarded as directly due to the introduction of the tube. In 5 cases hæmolytic streptococci were cultivated; in 4 of these the puerperium was afebrile throughout, but in one case febrile symptoms developed; these remained limited to a superficial infection of the endometrium. It must, therefore, be acknowledged that streptococci, indistinguishable from those found in severe forms of infection, may exist in the lochial discharge of puerperal women, even in the early days of the puerperium, without causing any rise of temperature. It is, therefore, not possible to claim that the hæmolytic forms an absolute distinction between the saprophytic and slightly virulent organisms and those which are pathogenic. If, however, hæmolytic streptococci are discovered in a case of fever after delivery, it is probable that they are the causal agents of the infection.

Hypernephroma of Broad Ligament, probably Ovarian.

—Gardner and McCleary (Surg., Gyn., and Obst., VII., 6).—The patient, set. 40, and multiparous, had not menstruated for seven or eight years. Two years

ago she noticed a tumour in her abdomen, which rose above the pelvic brim to the left of the middle line. At first there was no pain, but as the growth developed from time to time there were severe pains originating in the pelvis and radiating in all directions. Examination revealed a large, hard mass, occupying the greater part of the lower half of the abdomen and projecting into the pelvis. The tumour was very irregular in contour, and presented a distinct nodule about the size of a hen's egg on its upper anterior aspect. There was free fluid in the abdomen, and the mass displaced the uterus downwards. The abdomen was opened a little to one side of the middle line; it contained a large quantity of dark fluid. The surface of the tumour was nodular and traversed by many large veins. Owing to the numerous and strong adhesions which bound it to the pelvic and abdominal structures, much difficulty was experienced in freeing the tumour. There were several quite large cysts in the growth, and the walls were very friable. Nothing that had the appearance of an ovary was discovered, and it was presumed that the growth had started in the hilum of the ovary and extended into the broad ligament. The patient convalesced rapidly. A year later she was re-admitted to hospital with a recurrence of the tumour. On examination a mass very similar to, but not so large as the one removed was felt projecting above the brim of the pelvis to the left of the median line. On opening the abdomen a rounded mass was found in the region of the broad ligament on the left side, which measured 10 by 13 cm. It was densely adherent to the intestines, to the pelvic wall, and to the side of the uterus. The tumour was removed, and the patient was in good health, with no signs of recurrence a year later. Histo-pathology.—The oviduct which was attached to the gross specimen was perfectly normal, and although two dozen or more sections were taken from various parts of the tumour, no evidence of ovarian tissue could be found. Whether the tumour began in the broad ligament or primarily in the ovary could not be stated. Sections from the denser areas show either columns or circular islands of epithelial cells suggesting the structure of the glomerular and fascicular zones of the adrenal. The recurrent tumour was microscopically a perfect reproduction of the original growth, and indistinguishable from it. The growth was evidently a hypernephroma in the broad ligament, and probably originated in the ovary.

Temporary Ventro - Suspension of the Uterus.—Ochsner (Surg., Gyn., and Obst., VIII., 1).—The indications for this operation are on cases with large pelvic abscesses, where large denuded surfaces are bound to remain after the evacuation of the abscess and removal of the infected organs; also in cases of pyosalpinx, ovarian abscesses, old extra-uterine pregnancies, and appendical abscesses with leakage into the pelvis, in which the uterus shows a marked tendency to fall back into the pelvis when all the intraabdominal work is completed. The technique of the operation is as follows:—In laparotomies, when it seems probable that this temporary ventro-suspension will be desirable, the laparotomy incision is made so that at the lower angle the skin incision is distinctly the longest, then the fascia, and muscle, and the peritoneal wound the shortest. After the intra-abdominal work is finished, a needle armed with a double strand of ten-day catgut is introduced through the left rectus fascia about half-an-inch below the lower angle of the fascial incision, then through the left muscle and the peritoneum about an inch below the peritoneal incision. It is now passed through the uterus about an inch behind the apex of the uterus, taking a good bite and being careful not to abrade the peritoneum covering the uterus. The needle is then passed out in the reverse order on the right side to its introduction on the left, and the suture is tied just tight enough to bring the vterus in contact with the abdominal wall, but not to Cause destruction of the peritoneum from pressure. The sigmoid is now carefully placed behind the uterus and the omentum spread over this, covering all the raw surfaces which it may have been impossible to cover with peritoneum. The abdomen is then closed. most important point is to get the unabraded uterus in contact with unabraded peritoneum; then there are only two needle holes on either side where the peritoneal continuity is broken. During the years 1906 and 1907 the author performed this operation 32 times. In no case which he has subsequently examined has he found the uterus permanently suspended or adherent posteriorly. On three cases secondary operations were done about 15 months after the primary operations, all being ovarian abscess or pyosalpinx cases. In two the uterus was perfectly movable and free from adhesions. In the third the uterus was slightly adherent to the sigmoid, but fairly movable. The author maintains that by temporarily suspending the uterus in this way the objections to fixation are done away with, and the round ligaments, by being relieved of the constant overstretching due to retroversion of the uterus, regain their tone and become actively functional again in retaining the uterus in its normal position.

Eclampsia and Toxemia of Pregnancy.—Welch. (Amer. Journ. of Obst., LIX., 1). The author, quoting from Whitridge Williams, writes: "From a pathological point of view, the lesions in the two conditions differ so markedly that I do not see how it is-possible for anyone who has once observed them to consider that they are at all related. In eclampsia, as was first pointed out by Jurgens, Schmorl, and others, the lesion consists in hæmorrhagic necrosis occurring in the portal spaces, dependent upon thrombotic processes in the smaller portal spaces, and their mere presence justifies the diagnosis of eclampsia. On the other hand, in the liver lesions accompanying the toxæmic vomiting of pregnancy, the changes are purely degenerative in character, and begin in the central vein of the lobule and gradually extend to the periphery." The other school, viewing the subject from the standpoint of chemical analysis of the products of metabolism excreted in the urine, consider the different forms of toxemia of pregnancy, including eclampsia, as very closely related, if not identical, conditions. The author records the history and pathological findings of twelve cases in which the diagnosis was made either of eclampsia or toxæmia of pregnancy. The bases of the diagnosis were the clinical manifestations exhibited before death. Ten of the cases were diagnosed eclampsia and two toxemia of pregnancy. On making a survey of the liver lesions, they are found to fall into four classes. The first class had hæmorrhagic changes in and about the portal spaces and contained six cases, four diagnosed as eclampsia and two in which no convulsions occurred, and were called toxæmia of pregnancy. The second class showed necrosis in the centre of the liver lobules. These cases clinically were called eclampsia, having had from eight to over fifty convulsions, and all died post-partum on the 3rd, 6th and 6th days respectively. The third class included one case of eclampsia; the liver showed no hæmorrhage, but a general swelling of the cells and autolysis. The fourth class, in which the liver changes were very slight, cloudy swelling of the parenchyma, with no hæmorrhage or necrosis contained, had cases both diagnosed eclampsia. kidneys in all cases showed very marked disintegration of their epithelium to about the same degree. parenchyma was markedly affected throughout the organs in all the cases, but varied in different parts of the same organ. Most of the cases showed considerable hæmolysis. The masses described as fibrin in the hæmorrhages of the liver did not appear as clearcut fibrins, but have a hyaline appearance, like fused red blood-cell stromas. The condition found in the parenchyma cells indicates the action of some dissolving poison, also capable of attacking the endothelium of the blood vessels. The author suggests that the numerous hæmorrhages are due to a poison circulating in the blood, which causes agglutination of the blood-cells, which then form emboli, and by solution of the endothelium allow the blood to escape. The poison causing this serious intoxication is probably an enzyme or combination of enzymes. Two possible sources are proposed for the poison—one the kidneys and intestinal tract, the other the placenta and fœtus. The author seems to incline towards the former; he concludes that under apparently similar conditions one

individual will, while another will not, have eclampsia, and thinks this fact may be explained by the side chain theory of immunity.

F.

Cardiac Disease as a Complication of Pregnancy.—Ryder (Amer. Journ. of Obst., LIX., 1). The author reviews the records of cardiac disease complicating pregnancy at the Sloane Maternity Hospital. 4,000 confinements between September, 1904, and April, 1907, he collected 56 cases of cardiac disease; this makes a frequency of 1.4 per cent. In 5,000 confinements immediately preceding this series 36 cases of cardiac lesions were recorded, but in this series many of the milder cases were not recorded. These two series give a total of 92 cases. Mitral insufficiency was most frequent, 49 cases (53 per cent.), mitral stenosis 14 (15 per cent.), double mitral 15 (16 per cent), total mitral lesions 78 cases (85 per cent.), myocarditis 5 cases (5.4 per cent.), aortic insufficiency and aortic roughening 3 cases each (3.2 per cent.), malignant endocarditis with ulceration 1, marked tachycardia 2. The total maternal deaths in the series of 92 cases was seven (7.6 per cent.), three were with myocarditis, two th mitral insufficiency, one with double mitral, and one with malignant endocarditis. All the deaths occurred after labour, and, with one exception, within a few hours. In 32 of the series there were absolutely no symptoms. In 24 slight symptoms, calling for no treatment. In 8 treatment was necessary for obstetrical Thus in 64 cases no treatment was complications. needed for the heart lesions. In 28 cases there was failing compensation and treatment was needed. All the maternal deaths occurred in this number seven in 28 cases (25 per cent.). There were in these 28 cases 13 foetal deaths and 22 premature endings of pregnancy, but all artificial. A study of these cases show that the frequency of heart lesions in pregnancy was 1.4 per cent. Mitral lesions were by far the most common, nearly 5 per cent. Myocarditis the most fatal. Mitral stenosis and aortic lesions caused no deaths. Premature labour or abortion was common, about one in twelve, where there was no interference. The author draws the following conclusions: -Cardiac disease is a frequent complication of pregnancy. The crucial point to be considered is whether or not the heart is well compensated. During pregnancy the patient should be guarded against sudden chilling, as this is apt to cause congestion of the lungs and kidneys, and thus throw extra work on the heart. During labour great care should be taken not to let the patient over-exert herself. The first stage should be shortened by bags or bougies, and the second stage especially hastened by forceps or other means. As to chloroform, these patients stand amount well, and are benefited by it, prolonged use is harmful. With any tendency to pul-monary congestion ether is contra-indicated. With failure of compensation, under the most favourable conditions and the best treatment, the maternal mortality is 1 in 4, and the fœtal about twice as much. Treatment should not be delayed; the patient should be put to bed on light diet and heart stimulants. If, in spite of treatment, failure of compensation is more marked, termination of pregnancy should be considered. During labour the heart must be strengthened and supported, the patient quieted, and labour shortened. Morphine in small repeated doses is especially useful, as it lessens the pain, quiets the patient, and steadies the heart. Bags to hasten the first stage are useful, and forceps should be applied as soon as they can be used safely. The third stage may often be shortened with advantage. After labour, within a few hours is the time most fatalities occur. The patient should be placed in bed as soon as possible. Heart stimulants should be freely used as indicated. Morphine is of the greatest value; a full dose immediately after labour does more good than almost any other drug.

A Typhoid Carrier.—Cochrane (R.A.M.C. Journ., February, 1909) details the investigation of an outbreak of enteric fever at Aldershot during last year in which the infection was traced to a "carrier." Four patients were admitted to hospital with enteric fever during the

first three weeks of September from the 1st Battalion of the East Kent Regiment. These patients occupied adjoining rooms in the same barracks, but had recently been on furlough, and were believed to have brought the infection with them to barracks on their return, as no likely source of infection could be detected in the barracks During the following month 123 men of another regiment were accommodated in these barracks in rooms adjoining those from which the patients had previously come. These men, though occupying these rooms, were provided with a separate cook-house. Two of them eventually sickened with enteric fever. It then became evident that the infection of all the cases was probably derived from the special rooms the men occupied, for there was no tendency of the disease to spread to other men whose food supply was derived from the same source. It was then found that out of the two companies which occupied these rooms nine men had recovered from enteric fever on dates varying from 1895 to 1907. Cultures were made from the urine of each of these men, and from one of them a bacillus was recovered which proved to be the bacillus typhosus. This man had left hospital after an attack of enteric fever in November, 1904. It was found that since that time some ten or twelve men who were associated with this man had developed enteric fever. This man has now been isolated and is undergoing treatment, so it will be interesting to see if his removal will check the incidence of the disease in the company with which he was connected.

The Spirochæta Pallida and Congenital Syphilis.—M'Intosh (Journal of Pathology and Bacteriology, January, 1909) publishes a careful study of the distribution of the spirochæta pallida in the body in congenital syphilis. It is to be found in greatest numbers in the liver, but it is also present in the lungs, the spleen, the suprarenal gland, the kidney, and the skin. In the skin, as in the liver, it is in enormous numbers. M'Intosh failed to find it in the placenta or in the umbilical cord. He argues that the infection is maternal, that the spirochætes are carried in the blood to the liver, where they multiply, and whence they are distributed to the rest of the body. The organism has a special affinity for structures of the nature of consective tissue or glandular epithelium, and it is specially plentiful in the connective tissue round blood vessels. The relation of the spirochæte to congenital syphilis is very constant, and, admitting its causality, the presence of the organism furnishes an easy diagnosis.

Human Glanders .- Bernstein and Carling (British Medical Journal, February 6th, 1909) report six cases of glanders in the human subject, and discuss the methods of diagnosis. They believe the disease to be much more common than would appear from the statistics of the Registrar-General. The symptomatology of the disease is very variable, and the authors believe that the mere fact of a patient's occupation being such as to bring him into contact with horses, and the occurrence of a chronic inflammatory lesion of the oral or nasal mucous membrane, or of an inflammatory mass in the subcutaneous or muscular tissue, should be sufficient to suggest the disease to the surgeon's mind. In diagnosis, reliance is to be placed on the mallein test, both positively and negatively. Occasionally the reaction may be severe—pain, malaise, and a rigor being among the phenomena noted. The dose used was the usual one for horses-10 to 15 minims. Animal inoculation also gives information. Adult male guinea-pigs should be employed, the inoculation being intraperitoneal or subcutaneous. It is difficult to find the bacilli in smears from the pus of glanders, as they are difficult to stain, and negative to Gram's method. On the other hand, cultures grow easily and are characteristic. The authors attempted to apply the agglutination test in one case, but did not obtain any definite results.

#### THE MEDICAL PRES

#### MEDICAL NEWS IN BRIEF.

#### The Dental Hospital of Ireland.

The annual meeting of the supporters of and subscribers to the Dental Hospital of Ireland was held during the past week, when the Honorary Secretary, Mr. G. M. P. Murray, and the Dean, Dr. A. Baker, were able to present satisfactory reports of the work done by the hospital and of the school. The Dean referred in his report to the necessity for completing the building of the hospital during the coming summer, as, in consequence of want of space, they were obliged to turn away students. The necessary space for the proposed additions had been got from Trinity College, and all that was wanted was the £2,500 which the additional building would cost. The Chairman of the meeting said that the extension was absolutely necessary, and they were most anxious to begin it.

#### Compulsory Irish in the New National University.

WE published last week a memorial, signed by some 73 students of the Catholic University School of Medicine, protesting against compulsory Irish in the new University. A counter-memorial has now been issued and signed by some 200 students in the following terms:—

"We, the undersigned students of the Catholic University School of Medicine, present the following memorial to the Senate of the National University of Ireland:—We earnestly desire that the Irish language may be recognised as a fundamental element in the Higher Education of Irish Students. We, therefore, urge that a knowledge of Irish should be required of all Irish students at entrance to the University, and that the fullest opportunities and inducements be offered to students to continue the study of Irish in the University. We are also of opinion that a knowledge of Irish History should be required side by side with that of the Irish language."

#### Late Chieroform Poisoning.

THE evidence given at an inquest on February 19th concerning the death of Dorothy Abery, the six-and-a-half years' old daughter of a labourer living at Rochford, Essex, showed that the child had been unable to speak or walk from birth, and on February 19th was removed to the Great Ormond Street Hospital for Children. An operation under chloroform was performed on the child's throat. It was successful, and the girl made satisfactory progress till the next day, when she became ill, and died in 24 hours. Dr. Gray, Medical Superintendent of the hospital, said that a small dose of chloroform was administered. Death ensued from coma and heart failure, due to delayed chloroform poisoning, whilst the child was of low vitality. Mr. Schröder (the Coroner): The question of delayed chloroform poisoning has not been established many years? Dr. Gray: That is so. It was not due to the quantity of chloroform administered, but to the condition of the patient. A verdict of death from misadventure was returned.

#### Cocaine Poisoning in a Child.

An inquest was held at Derby, on February 18th, concerning the death of Rose Earl, aged 8 years. Dr. Flora Morrison said it was decided to use a local anæsthetic for removal of the tonsil in consequence of the child's low condition. Witness painted the tonsil, but the operation was performed by Dr. Shepherd. The Coroner: Was a portion of the cocaine swallowed by the child?—Not swallowed; it would be absorbed. And in consequence get into the intestines —No, into the general circulation. What effect would that have on her?—It would have a weakening effect upon the heart. What quantity of cocaine would stop the circulation of the heart's action?—I should think there would be three-quarters of a grain in this case, not more. Witness added that Dr. Shepherd removed the tensil in witness's presence. The child was not unconscious at any time. She was a little frightened at the thought of the operation, but recovered after it was performed. She then became perfectly rigid in an

epileptic fit, and sank into unconsciousness. She had ten fits altogether after the operation, and died in one. The Coroner: What would bring about these fits?—The absorption of cocaine. Would three-quarters of a grain be sufficient to kill in a normal case?—No; but this was not a normal case. The operation was properly and skilfully performed. The cause of death was the absorption of cocaine, and the operation proper had nothing whatever to do with it. Dr. Shepherd entirely agreed with the previous witness, and added that it was most unusual for three-quarters of a grain of cocaine to kill. The jury returned a verdict in accordance with the medical testimony, and added a rider to the effect that everything was done that was possible, and that no blame attached to anyone

#### National Tuberculosis Conference.

The concluding day of the National Conference on Tuberculosis, at the Caxton Hall, Westminster, was formally opened by Lord Kinnaird. Sir John Kirk presided. Lord Kinnaird said, in regard to the milk supply, that it was with considerable interest they awaited the publication of the text of the measure dealing with that matter mentioned in the King's Speech at the opening of Parliament. It was essential that the general public should be better informed on the subject of tuberculosis before any attempt was made to introduce such reforms as compulsory notification. He also referred in appreciative terms to the work done by Lady Aberdeen in Ireland. Dr. Rutherford, M.P., said that a great deal could be done in such matters as housing and town planning, and in restricting the alcoholic environment of the people. In the Poor-law Report there was the foundation for legislation in the future which would help in the protection of the children, on whom depended the prosperity of the race. At the afternoon session other papers were read, and a conversazione was held in the council chamber in the evening.

#### The Late Mr. W. H. Kendall.

On the 18th ult., additions to the Lying-in Hospital, Kingsdown, Bristol, were dedicated by the Bishop of Bristol, accompanied by Archdeacon Stewart, Canon Everingham, Canon Talbot, and others. Dr. Elliott explained that a portion of the additions to the building was known as the "Kendall Memorial," in memory of Mr. Kendall, who was recently honorary surgeon of the institution, and through whose instrumentality the extensions had taken place. A tablet in one of the wards bears the following inscription:—"This tablet gratefully records seven years' honorary faithful and efficient services rendered to the patients of this institution by Herbert William Kendall, F.R.C.S., L.R.C.P., who fell asleep December 22nd, 1906, aged 39. This ward has been furnished by grateful patients and friends as a mark of esteem."

#### The Royal Society of Medicine.

THE following members of the Odontological Section of the Royal Society of Medicine were elected as Officers and Councillors for the year 1909:—

President.-Leonard Matheson.

Vice-Presidents.—Resident: H. Lloyd Williams, C. F. Rilot, A. Clayton Woodhouse. Non-Resident: Martin Henry (Folkestone), J. McKno Ackland (Exeter), Edward Bogue (New York).

House and Finance Committee.—H. Lloyd Williams. Library Committee.—Ashley Densham.

Curator.—J. F. Colyer.

Editorial Committee.—A. Hopewell-Smith.

Hon. Secretaries.—J. Howard Mummery (Foreign), H. W. Trewby (Council), Douglas P. Gabell (Society).

Councillors.—Resident: Alfred Stevens, Norman G. Bennett, W. S. Nowell, F. Lawson Dodd, W. J. May, J. G. Turner, J. Lewin Payne, H. E. Cribb. E. B. Dowsett. Non-Resident: F. C. Porter (Nottingham), J. Royston (Liverpool), W. E. Margetson (Dewsbury), Herbert Williams (Londonderry), G. A. Peake (Cheltenham), W. de C. Prideaux (Weymouth), C. A. Havman (Bristol), G. R. Shiach (Elgin), S. G. Yates (Hereford).

#### NOTICES TO CORRESPONDENTS, &c.

Commercements requiring a reply in this column are par-ticularly requested to make use of a Distinctive Signature or Institut, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much con-fusion will be spared by attention to this rule. SUBSCRIPTION &

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January lat and July lat respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messra, Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messra, Dawson and Sons are our special agents for Canada.

ADVERTICEMENTS.

TERMO.—The origin of the association of the ancient professions of the barber and the surgeon took place in 1163. Up to that time surgery, such as it was in Europe, was almost entirely in the hands of the Jews and the olergy. The clergy employed barbers as their assistants in the application of baths and oluments, and hence in the performance of such surgical operations as they were in the habit of performing. In 1163, however, the clergy were prevented by a Papal prohibition from undertaking any operation which involved the shedding of blood. The Jews had largely disappeared, probably owing to the increasing prejudice against their race, and so the barbers were left as a class with a certain familiarity with surgical technique and connection with the art. The only trace of this alliance that now remains is the barber's sign, the red and white striped pole, which is the symbol of the barber in his surgical, not in his tonsorial, capacity. In the days of blood-letting the barbers displayed outside their shops the staff which the patient grasped in his hand during the operation, wrapped round with the blood-stained bandages, and these actualities were later replaced by the symbolic emblem which still adorns our streets.

The "Lemco" or Liebig's Extract of Meat Company, Ltd., offers

replaced by the symbolic emblem which still adorns our streets.

The "Lemco" or Liebig's Extract of Meat Company, Ltd., offers a Thermos flask to clients on condition of their receiving before December 1st, 1909, weight coupons, to be found under the capsule of each jar, representing 7-lbs, of Lemco, when the flask will be sent by return. The flask may be sent sooner by sending 5-lbs, weight coupons and a returnable deposit of 7s. 6d. The flask is worth £1, and the scheme represents commendable enterprise on the part of this well-known firm.

A. B. V.—We are sorry to say we never heard of it. Probably it has not yet reached a position other than experimental.

#### Meetings of the Societies, Tectures, &c.

WEDNESDAY, FEBRUARY 24TH.
HUNTERIAN SOCIETY (London Hospital, Whitechapel Road, E.).—
p.m.: Clinical meeting.
ROTAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, V.C.).—5 p.m.: Prof. W. Wright: The Morphology and Variation W.C.).-5 p.m of the Skull.

5.15 p.m.: Lecture: Pr. L. Williams: Some Climacteric Disturbances.

North-East London Post-Graddata College (Prince of Wales's General Hospital, Tottenham, N.)—2.30 p.m.: Gynecological Operations (Dr. A. E. Giles). Clinics: Medical Out-parient (Dr. A. J., Whiting): Surgical (Mr. H. W. Carson); N. Rays. 5 p.m.: Medical In-patient (Dr. G. P. Chappel). 4 30 p.m.: Lecture: Dr. A. G. Auld: Difficulties encountered in the Physical Examination of the Lungs and Heart.

St. John's Hospital. for Direases of the Skin (Leicester Square, W.C.)—6 p.m.: Clesterfield Lecture: Baldness, its Causes and Treatment.

Feidar, Ferrurar 26th.

Rotal Society of Medicine (Section for the Stidt of Disease in Children) (20, Hanover Square, W.).—5 p.m.: Cases Dr. Edmund Cautley: (1) Cerebral Dipligic Spacticity; (2) Abdominal Tuberculosis; (3) Mongolian Imbecile (2). Dr. F. J. Poynton: Case for Diagnosis. Mr. Nother Stephenon: Plexiform Neuroma involving the Right Parietal Region and Right Upper Evelid. Dr. O. F. F. Grundbaum: Case of Hirschsprung's Disease, Discussion: On the Medical Examination of School Children Opposed by Dr. George Carpenter).

BOTAL SOCIETT OF MEDICINE (EPIDEMIOLOGICAL SECTION) (20, Hanover Square, W.).—8.30 p.m.: Dr. H. de R. Morgan and Dr. J. C. G. Ledingham: The Bacteriology of Summer Diarrhoea Dr. J. C. G in Children.

in Children.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5 p.m.: Prof. W. Wright: The Morphology and Variation of the Skull.

MEDICAL GRADUATES COLLEGE AND FOLYCLINIC (22 Chenics Street, W.C.).—4 p.m.: Dr. J. Horne: Clinique (Throat).

NOBTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinic: Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Operations: (Mr. W. Edmunds). Clinics: Medical Out-patient (Dr. A. G. Auld); Eye (Mr. R. P. Brooks). 5 p.m.: Medical In-patient (Dr. R. M. Leslie).

CENTRAI, LONDON THEOAT AND EAR HOSPITAL (Gray's Inn Road, W.C.).—3.45 p.m.: Lecture: Dr. Abercrombie: Pharynx and Nasopharynx.

TUESDAY, MARCH 2ND.

pharynx.

TUESDAY, MARCH 2ND.

ROYAL SOCIETY OF MEDICINE (THERAPEUTICAL AND PHARMACOLOGICAL SECTION) (20, Hanover Square, W.).—4.30 p.m.:

A Discussion on the Treatment of Spasmodic Asthma, to be
opened by Dr. Cecil Wall.

BALLANTINE, S. A., M.B., Ch.B.Edin., F.R.C.S.Edin., Honorary Surgeon to the Coventry and Warwickshire Hospital. CARY, ARTHUR JAMES, L.R.C.P., L.R.C.S., L.M.Irel., Medical Officer for the Fourth District of the Axbridge (Somewet)

Ufficer for the Fourth District of the Arbridge (Somerfiet)
Union.

FURBEY, F. R., M.B., C.M., Clinical Assistant to the Chelsea
Hospital for Women.

GLENDINING, BRIDEN, M.B., B.S.Durh., F.R.C.S.Eng., Pathologist
to the Chelsea Hospital for Women.

LECRE, ARTHUR. M.R.C.S., L.R.C.P.Edin., Medical Officer of
Health of Arbridge (Somerset).

MOORE, C. A., M.S., M.B.Lond., F.R.C.S., Senior House Surgeon
at the Bristol General Hospital.

PINEO, ERNEST GEORGE DUUGLAS, L.R.C.P.Lond., M.R.C.S.,
Medical Officer for the Churchill District of the Arbridge
(Somerset) Union.

ROSS, DONALD, M.B., Ch.B.Edin., Assistant Medical Officer at the
RONBURGH DISTRICT ASPURM, Melrose.

SCOTT, MALCOLM L., M.B., Ch.B., Clinical Assistant to the Chelsea
Hospital for Women.

#### Vacancies.

Parish of Gairloch (Southern Division).—Medical Officer. Salary, £150 per annum. Applications to the Clerk to the Parish Council, Poolewe.

County Palatine of Chester.—Medical Officer of Health. Salary, £750 per annum, with travelling and hotel expenses. Applications to Reginald Potts. Clerk to the County County Offices, Northgate Street, Chester.

Rhondda Urban District Council.—Assistant Medical Officer of Health. Salary, £250 per annum. Applications to W. P. Nicholas, Clerk to the Council, Council Offices, Pentre. Rhondda.

Cancer Hospital (Free), Fulham Road, London, S.W.—First Assistant to the Research Department. Salary, £350 per annum. Applications to Fred. W. Howell, Secretary.

Durham County Asylum.—Junior Assistant Medical Officer, Salary, £150 per annum, with board, laundry, and attendance. Applications, immediately, to the Medical Officer of Health. Salary, £500 per annum. Applications to H. J. Baker, Clerk to the Council. Council House, Houselow.

York Dispensary.—Resident Medical Officer. Salary, £130 a year, with board, lodging, and attendance. Applications to Dr. Swanson, The Pleasaunce, Heworth, York.

#### Births.

Cowan.—On February 19th, at 32, Fitzroy Square, London, the wife of Dr. Horsee Cowan, of a daughter.

MASINA.—On Feb. l. at Warden Road, Malabar Hill, Bombay, India. the wife of H. M. Másiná, F.R.C.S., of a son.

#### Marriages.

ORTON-COATES.—On Feb. 20th, at Eye Church, Leominster, Ernest Henry, youngest son of G. H. Orton, M.B., F.R.C.S., of 7 Campden Hill Road, Kensington, to Fmily Beach, second daughter of C. W. Coates, of Osborne Park, Belfast.

#### Beaths.

ALL.—On February 20th, at Cannes, of pneumonia, Dr. Robert Henry Coall, late of 65, Brook Street, Grosvenor Square.

Henry Coall, late of 65, Brook Street, Grosvenor Square, London.

FLEMING.—On Feb. 19th, at Clyde Lodge, Caterham Valley, Robert Gage Fleming, M.D., late of Thornton Heath, aged 61.

Hamilton.—On February 19th, at 35 Queen's Road, Aberdeen, David James Hamilton, M.B. LL.D., F.R.S., Emeritus Professor of Pathology in the University of Aberdeen, fessor of Pathology in the University of Aberdeen, Mrs.—On February 17th, at 17 Gloucester Walk, Campden Hill, Thomas Radford King, F.R.C.S., M.D., from heart failure, after three days' illness, Routh.—On February 19th, at 52 Montagu Square, London, Charles Henry Felix Routh, M.D.Lond., M.R.C.P., aged 87, Styton.—On February 17th, at 37 Denbigh Street, Warwick Square, London, in her 96th year, Charlotte, widow of John Sutton, Esq., M.R.C.S.

## Peptogenic Milk Powder

Cows' milk prepared with PEPTOGENIC MILK POWDER becomes remarkably like mothers' milk in all particulars: in physical properties, in colour and taste, and in the percentage of nutritive constituents: in its digestibility, its behaviour with acid, with rennet, and in the infant's stomach.

Milk prepared with the PEPTOGENIC POWDER has simply the normal digestibility of mothers' milk: is not too easily or unnaturally digestible, and contains no aid to digestion. It affords a complete substitute for mothers' milk during the entire nursing period.

Supplied to the Medical Profession in two sizes, at 1/10 and 3/8 each.

## 'Pepsencia'

PEPSENCIA is an ever-ready digestive fluid possessing remarkable peptic and rennet activity. It contains pure pepsin, the vitality of which is unimpaired by chemical action or manipulation, and it is obtained by direct solution from the secreting glands of the gastric mucous membrane, every care being exercised to preserve its full physiological activity.

The usual dose is a teaspoonful before or after meals in all cases where pepsin is indicated. Supplied to the Medical Profession in 4 oz. and 8 oz. bottles, at 1/10 and 3/3 each.

## 'Panopepton'

PANOPEPTON presents the entire substance of prime lean beef and best wheat flour in a perfectly soluble, diffusible, and absorbable form. It is at once a grateful stimulant and food.

For an adult, the usual portion should be a dessertspoonful to a tablespoonful several times a day and at bedtime.

Supplied to the Medical Profession in 6 oz. and 12 oz. bottles, at 2/2 and 3/8 each.

Specimens and literature will be forwarded on request.

Originated and Manufactured by

Fairchild Bros. & Foster, NEW YORK. Agents for Europe, Asia, Africa, and Australasia:

Burroughs Wellcome & Co., LONDON, SYDNEY. CAPE TOWN

## **EVIDENCE**

N EXPERT comparative analysis of the principal Cocoa preparations reveals the fact that VAN HOUTEN'S is much more readily digested than any other kind.

The remarkably fine state of sub-division of the powder renders it perfectly miscible and no sediment remains in the cup.

VAN HOUTEN'S COCOA is therefore pre-eminently suitable for invalids, and does not tax the weakest digestive organs. It never varies in quality and can be confidently recommended as a nourishing, sustaining, and strengthening beverage of the highest standard of purity.

80 years reputation as "the BEST."

The Best and Goes Farthest

# Influenza and its Sequelæ.

The antiseptic, soothing and tonic properties of Angier's Emulsion eminently adapt it to the treatment of the catarrhal symptoms, whether tonsillar, bronchial or intestinal, which so generally follow the more acute stage of Influenza. It is most efficacious in relieving the troublesome laryngeal, or tracheal cough, while it also allays the dangerous symptoms of congestion and inflammation of the respiratory organs and obviates the tendency to pneumonia and pleurisy. Moreover, the hypophosphites in the Emulsion combat the nervous depression and tone up the nervous system generally. After a serious attack of Influenza when the patient's nutrition and vitality are at the lowest ebb try the continued use of Angier's Emulsion for a convincing proof of its effects as a tonic and reconstructive.

# ANGIER'S EMULSION

(Petroleum with Hypophosphites.)

#### Debility After Influenza.

Liverpool, Feb. 17th, 1909.

Dear Sirs,—I have prescribed Angier's Emulsion for about sixteen years and have found it a valuable help in many cases of debility after influenza, pneumonia, pleurisy and bronchitis. I have also had good results from its use in intestinal trouble in children. It is palatable and can be taken when cod-liver oil causes nausea.

(Signed) ——, L.R.C.P., L.R.C.S., &c.

#### Cough Following Influenza.

Dear Sirs,—I have used Angier's Emulsion in a number of chest cases, notably in cough following influenza and in the later stages of bronchitis in children, and have never known it to fail. In one case of advanced phthisis it gave a good deal of relief. After trial in a multitude of chest cases, I consider it far superior to all other emulsions.

(Signed) ---, L.R.C.P., L.R.C.S.

FREE SAMPLES TO THE MEDICAL PROFESSION.

# STYPTOL

An opium derivative which has proved to be a more reliable and more efficient drug in the various forms of uterine hæmorrhage than hydrastis, hamamelis, ergot, &c. It has proved especially effective in cases of severe

### Menorrhagia and Dysmenorrhœa

It is also beneficial in metrorrhagia, threatened abortion, after operative measures, in climacteric hæmorrhage, and in new growths. It relieves pain and prevents inflammation, and is free from any injurious action on the heart or the digestive apparatus. As it never causes contractions, it can be administered with safety during pregnancy.

Dose: 2-3 tablets (3 grain each) ter die.

Price: 1/1 per tube of 20 tabs.

Samples and Literature on application.

KNOLL & CO., 8 Harp Lane, London, E.C.

## Hemaboloids

contains Iron combined with vegetable nucleo-proteids, closely approximating the natural foodform, reinforced by Peptones, Bone Marrow Extract and Nuclein.

It is in palatable, stable, non-irritating solution, does not constipate, and can be absorbed and assimilated by the most delicate stomach.

One tablespoonful contains the Iron equivalent of 20 Minims Tr. Ferri Chlor. Is indicated in all non-febrile Anemias, Adynamia after fevers, Brights Disease, Diabetes, Chronic Bronchitis and Emphysema, Cardiac disease, Neuralgias, Protracted Convalescence, etc.

DOSE: One tablespoonful 3 or 4 times per day.

Furnished in 12 oz. bottles 5½ oz. bottles

#### ANDRUS & ANDRUS

3 Lloyd's Avenue, London, E.C.

## Valentine's Meat-Juice

Whenever the Stomach, from any cause, rejects food or medicine, Valentine's Meat-Juice can be relied on to be retained and to Nourish and Sustain when other forms of food fail.

In low forms of Pneumonia and Exhaustion, in the General Debility with Impaired Digestion of Phthisis, and in the Depressing Prostration following Influenza, it is recommended by practitioners throughout the world as invaluable in their treatment.

#### Pneumonia, Phthisis and Influenza.

Frank Van Fleet, M. D., Professor Diseases of the Eye, Post-Graduate Medical School and Hospital, New York: "I was unfortunate enough to contract double Pneumonia last winter, which was followed by double Pleurisy and Empyema. During several weeks of unconsciousness I was nourished (after milk had begun to disagree with me) with Valentine's Meat-Juice exclusively."

Prof. Dr. M. Litten, Lecturer on Internal Medicine, University of Berlin, and Director of the City Hospital, Berlin, Germany: "I have employed Valentine's Meat-Juice with patients suffering from Tuberculosis, and observed excellent results from its use. I have also used it with good results in the treatment of patients with Anæmia, as well as those convalescent from acute diseases."

R. B. Watson, M. D., Surgeon Pennsylvania Co. and Lockhaven Hospital, Lockhaven, Pa.: "The results obtained from the use of Valentine's Meat-Juice establish all that is claimed for it. In a case of Phthisis it alone kept the patient alive for weeks, as it was the only nourishment she was able to take."

J. W. Dalrymple, M. D., Medical Director Riverview Sanatorium, New York: "It is with pleasure that I add my testimonial to the great value of Valentine's Meat-Juice in my hands during the recent epidemics of Influenza in this city, sustaining, as it did, the vital powers of the patients beyond the crisis and through convalescence, without their experiencing any degree of prostration."

Physicians are invited to send for brochures containing clinical reports.

For Sale by European and American Chemists and Druggists.

#### Notes and Comments.

THE breakdown in the administra-The Deadlock tion of the Midwives Act is deplorin the able, but the blame certainly does Midwives Act. not lie upon the medical profession. Parliament has rarely, if ever, been generous, let alone just, where the payment of medical services is concerned. The last notable instance in which the Government exacted purely gratuitous work from medical practitioners was in the notification of births, which is not only an unpaid, but a compulsory duty. The fact is gradually becoming known, however, that Parliament made a fatal error in not fixing for the payment of medical men called in to the help of that newly-created hybrid practitioner, the certified midwife. There is a limit even to the open-hearted generosity of the medical profession, and it can hardly be wondered if the average practitioner declines to attend at a midwife's behest a case where his fees are not guaranteed. A valuable source of his modest income has been diverted into unquali-fied channels, and it is asking too much of human nature to demand his skill and services without proper remuneration. For his skill and his time are his livelihood, a plain fact that is apparently overlooked by the public and by the legislature that have long grown accustomed to acts of selfabnegation and unselfish generosity on the part of medical men. All that has been repaid by the creation of the certificated midwife. The circumstances of the situation have been changed, and it is natural enough that the general practitioner should assert his right to revise his own attitude with regard to the vast amount of gratuitous work he has bestowed upon the woman in labour for many a year.

A Case at Sheffield. The whole question has been thrust in concrete form upon the inner consciousness of the good folk of Sheffield. A midwife who was called in attendance on a case said it was

one for a medical man, and forthwith left the house. The husband called upon four medical men, none of whom would attend unless the fee was forthcoming. Soon after his return home his wife died from hæmorrhage. It is difficult to see how the midwife could be justified in leaving a woman alone under what she obviously recognised as abnormal conditions of labour. The Coroner said the refusal of the doctors to attend seemed hard, but a medical man's skill was his capital, and they gave away without hope of return more of that capital than any other profession on earth. They went to hundreds of cases where they knew they would never be paid, and to hundreds of cases where they hoped to be paid, but never received

any money. The Sheffield Daily Telegraph has taken up the subject with its usual outspoken common sense. Says that journal, quoting a medical friend:—"There are hundreds of people who regard our profession as perfectly fair game. They think they have a right to call us in whenever they like, and to pay us or not just as they choose. And it arises very largely from out own cowardice and from the thoughtlessness of those who are better off." The rest of the communication runs as under.

" Our Own Fault." "COWARDICE!" echoed the *Telegraph*. "Just that," he responded. "Many doctors have not the moral courage to refuse a call; it may mean publicity and some amount of

denunciation which they dare not face. Then, again, there are doctors who have good paying patients who never send in a bill to their poorer clients. That is all right from their point of view, but it is terribly hard on the struggling practitioner. When doctors agree to say, 'We are professional men. Pay us, and our services are at your disposal. But no pay, no service,' we shall come to the end of this noxious business. But I do not blame the public. I blame my own colleagues. It is our own fault." The fact is, comments the editor, that a doctor is a professional man, just as a lawyer is, or a chartered accountant, or an electrical engineer. And he has a perfect right to demand payment for what he does. Whether a doctor would be right to refuse to go in answer to this particular call or that is a matter of individual circumstances. But he can do so if he choose. If he did so a little more frequently, and in some sort of combination, it is probable that the need for doing so would quickly disappear.

THE late Lord Beaconsfield, in his The dry epigrammatic manner, once re-Manifesto marked that he set no more store by Authoritative manifestoes than by the remarks chalked up on walls by urchins in the street. Like all epigrams, this expresses a certain side of the truth, and that side, we take it, is that the manifesto bearing the highest names is seldom representative of more than one phase of opinion, and is never final. At the same time, it is undeniable that such manifestoes must, and do. decidedly influence public opinion, and it is absolutely necessary sometimes to issue, as we ourselves did in the case of the late pro-alcohol manifesto, a counter-blast to show that authoritative opinion is not always on the same side. We have lately had another document, this time not technically a manifesto, but a signed letter, going the round of

the press, containing the condemnation by certain eminent members of the profession of long-distance running for school-boys. We cannot think that this method of "educating" the public is altogether happy or quite dignified. In the first place, it lays the signatories under the imputation of wishing to keep their names under the public eye, and even if done with the purest motives, there are always plenty of people ready to attribute this human failing to those who use the method.

Its Dangers.

THEN, again, after all, it merely expresses the opinion of the individuals signing, and the public are unable to judge whether in the question submitted the signatories are really

the right people to rely on. To them the fact that a man holds a Court appointment and has been dubbed knight or baronet is far more important than that he should have had actual large experience in the particular matter at issue. Moreover, there is a certain over-riding of the opinion of those-perhaps equally competent to judge (hence the value of counter-manifestoes)-who think differently. And, finally, the question cannot be discussed in the available limits of space in a manifesto, and consequently only a single argument or a blunt expression of opinion is possible. We think, then, that the leaders of the profession would be acting wisely and more in accordance with the healthy traditions of the profession if they eschewed this practice. It is an insidious one, and, like the sport of limericking, if it once gets hold of the profession, it may degenerate into a positive vice. Every medical man has his own opinion on medical subjects, and is entitled to it, but there is no reason for him to try to get it accepted, to the exclusion of those of his brethren, by being the first to "get it into the papers."

Mr. Lupton, M.P., has as sharp a Syphilisation nose for vaccine as ever Judge and Jeffreys had for a traitor, and last the Navy. week he unearthed one which should go far to recompense him for a

hundred snubs. It appears that last summer, at the annual meeting of the British Medical Association, a naval surgeon read a paper on anti-syphilitic inoculation, and he is said to have made the suggestion that men entering the Navy should be offered the opportunity of thus rendering them-selves immune to that disease. This was something after Mr. Lupton's own heart, especially as the virus was to be obtained from anthropoid apes, and he concocted a question to draw the First Lord, and it did, in fact, to some extent succeed, for it would appear that naval surgeons have to obtain their chief's approval before publishing scientific papers. That such a rule should exist is, we think, a pity, as in a liberal profession a man may differ very widely from current opinion, and yet should be allowed to express his views for what they are worth without implicating any-body but himself. That way progress lies. If medical science is to advance in the Army and Navy, it is obvious that many subordinates will differ from their superiors, without proper discipline or efficiency suffering.

Duties of Director-General.

THE duties of the Director-General of the Medical Department of the Navy should, therefore, be confined to the administrative side, and the purely scientific left, with due encouragement, to the enthusiasm of his subordinates. He should in no sense be bound, or associated with, views-heretical or ortho-

dox-published as scientific contributions by his officers. In the matter in question the naval surgeon who read the paper probably knows from practical experience far more of the horror and misery wrought by syphilis among bluejackets than Mr. Lupton or Mr. McKenna, and probably has given infinitely more thought to its prevention than either of these gentlemen. Even as civilians we know that the results, immediate and remote, are appalling. So that, without committing ourselves to any specific view of the proposed remedy, we may go so far as to say that it will be more becoming in them to criticise the officer when they have devoted as much attention to the subject as he has. Any honest effort, however mistaken, to prevent the gigantic evil, is deserving, at least, of respectful consideration.

#### LEADING ARTICLES.

#### PAYING PATIENTS IN CHARITABLE HOSPITALS.

The moot question of the propriety of the reception of paying patients in the wards of charitable medical institutions has been brought to the front in Liverpool, where recently a discussion has been raging on this debatable point. It was inaugurated at the annual meeting of the Royal Southern Hospital, held at the Town Hall on February 8th. On that occasion Mr. Charles W. Hayward, operating surgeon at the Hahnemann Hospital, called the attention of the trustees to the fact that in the Southern Hospital there were private wards to which private patients were admitted on a payment of two guineas a week for board and maintenance. but nothing was paid to the members of the medical staff who attended these cases. These patients, according to him, were all, or nearly all, prepared to pay. Several of them bore good names in Liverpool, and were thus under the stigma of receiving charity from the medical officer, if not from the hospital. Mr. Hayward dissented from the statement of Mr. Adamson, the President, to the effect that only the right class of case was admitted. This partial attack on the natural order of things produced an equally strong and pointed defensive reply on the part of the President. The latter read from a circular sent to every applicant for attendance in the private ward the following extract:-" The private wards of this hospital are for the use of poor persons who can pay two guineas per week towards their nursing maintenance, but who are unable to pay the specialists' fees for the treatment necessary for their cure. Persons who can pay those fees for treatment at home or a nursing home are not eligible for admission." That ground is intelligible enough, whatever view may be taken as to the justice of the transaction. Mr. Adamson, however, proceeded to make some general remarks upon the relation of honorary medical staffs to the hospitals which we are happy to think are not commonly introduced into public discussion by the chairmen of those institutions. After mentioning the fact that every patient admitted to the private ward was introduced by a member of the honorary staff or by a resident officer by arrangement with an honorary officer, he attacked the proposal to pay the medical attendants. It would be a "crying shame," he is reported to have said, if the medical man who used the hospital theatres or implements,

and took up the time of the nurses, should make any charge to the patients. We should like to ask Mr. Adamson is the hospital has any greater right to trade upon the theatres, and wards, and implements, and the nursing staff, to make money out of paying patients? The money having been subscribed to an institution for clearly-defined charitable purposes, it is not easy to see how the diversion of an eleemosynary gift to the forwarding of a purely business transaction can be justified. Least of all can we understand the line of reasoning which argues that everyone in the hospital concerned with the treatment of the paying patient—that is to say, house-surgeon, dispenser, nursing and domestic staff-should be paid, with the sole eception of the medical man, whose services are the central and indispensable proof of the whole affair. If, following the President's example, we reverted to plain English, the transaction might be described as "sweating" the honorary medical staff for the benefit of the hospital. The rest of Mr. Adamson's remarks were probably uttered in haste, for they seem hardly consonant with the dignity usually associated with the chairmanship of an important medical charity in one of the great cities of the Kingdom. He remarked that whenever a vacancy occurred on the honorary staff there was a struggle for the post among medical men. He quoted the recent statement of a London man, that it was worth £10,000 a year to get into a London hospital, to which he added-presumably his own estimatethat in Liverpool the indirect return would be £5,000. Whatever the case with eminent surgeons, either in London or in the provinces, the average income of the operating surgeon and successful specialist is certainly considerably below that mark, while that of the consulting physician has fallen of late years to an extent that has in many cases even threatened his survival. This disproportion of emolument will sooner or later doubtless lead to a readjustment of the fees and the field of work hitherto adhered to by physicians and surgeons. In any event, it is difficult to see how any responsible hospital executive can seriously defend the proposal to use the honorary services of the staff as a means of making money for the institutions concerned. The logical and right course, it has been urged in some quarters, would be to pay all medical men who serve the hospitals. There is much to be said in favour of that alternative, which appears to grow in favour with modern professional opinion. Certainly, so far as young consultants and specialists are concerned, the boon thus conferred would be in accordance not only with the diotates of common-sense, justice and propriety, but would be an inestimable aid to the first struggling years of practice. There are serious objections to the practice of the members of an honorary medical or surgical staff taking fees from patients in the pay wards of hospitals. The rights of the general practitioner are seriously invaded by such a practice, and where such an unwise usage has been established, the day of retribution will probably one day be at hand. The fact that there is no authoritative body entitled to speak out strongly and decisively on such important matters affords a striking testimony to the defective organisation of the medical profession of the United Kingdom.

THE SEQUELÆ OF MEDICAL INSPECTION.

One of the great difficulties of social reform is that it is almost impossible to predict the effect of a step ahead till the step has actually been taken, and though there are never lacking prophets of blessing and prophets of woe, their utterances have always to be discounted by the fact that no prophet can be judged except by posterity. There can be but little hesitation on the part of thoughtful people in admitting that the effects of two recent measures which were passed with general support, namely, the feeding of schoolchildren and their medical inspection, are merely stepping-stones to a vastly wider series of social responsibilities, and that the ultimate goal, which it is difficult logically to dispute, is the State care of the child. We presume that there are both good and bad sides to this ideal. The State would be better than a bad parent, but not nearly so good as a conscientious parent, and the scope of the reasonable function for the State would seem to be to encourage the latter by every legitimate means, while replacing the bad parents' shortcomings with care for the child and punishment for the offender. There, however, the question does not end, for though the bulk of parents are neither very good nor very bad, they are generally poor, and out of that poverty arises inability to do for the child what modern consideration for its welfare deems necessary. In nothing is this so well exemplified as in medical care. If doctors are to be efficient, they must be highly trained, and training of such a character as will fit a man to be a trustworthy adviser in sickness connotes a long and expensive education. So that medical attendance is bound to be expensive, at any rate, as regards the means of the unskilled worker. The problem has hitherto been carefully shunned by the State, and free charitable hospitals and the humanity of medical men have been left to do what they can for the With the advent of the systematic medical poor. inspection of school-children, however, a new and disconcerting factor has arisen. Children in shoals are found defective by the medical examiners in teeth, eyes, ears, and a dozen other attributes, and the parents receive official intimation of the fact, with a recommendation that dental and medical advice shall be sought. Three courses are open to recipients: to take no notice-which is apparently the most frequent; to call in their own doctor-which appears to be the least frequent; or to take the child to the hospital-which is sufficiently frequent to disorganise the normal routine of, at all events, some institutions. We admit the difficulty of the parent. To set in order, and to keep in order, the children's teeth is bound to be a matter beyond the means of a labourer earning As a week. Nor can it be expected that a club doctor can afford the necessary time and provide the necessary apparatus to take out the refractions of the eyes of a large number of children for whom he has to provide medical attendance and medicine at probably a penny per head per week. hospitals are already more than sufficiently patronised, and even if unsuitable applicants are winnowed out, there remain an enormous number of deserving ones who can only be dealt with as an expense which is proved to be beyond the means

charitable people are prepared to subscribe. The question of school clinics, therefore, has arisen, and whether this be the right solution or not, it is evidently one which the State, either by means of central or local authorities has to consider, and, if adopted, to pay for. A somewhat acrimonious debate took place at a meeting of the Education Committee of the London County Council last week on a proposal of the Royal Eve Hospital, which has already provided considerable facilities for treating the eyes of elementary school-children, still further to increase their accommodation if the Council would subsidise the extension. From the Council's point of view this would be a very cheap bargain, and yet the whole debate centred round the question whether they would provide the money themselves or extract it from the Chancellor of the Exchequer. That in itself is a municipal question with which we are not immediately concerned, but we do protest emphatically that if the public authority in charge of children needs medical advice for them, it is only right and fair that it should pay, whether the money comes out of taxes or out of rates. It is to us an insufferable suggestion that any public authority should cast its responsibilities on the shoulders of medical men without payment. It has been done time and again, and will be done as long as medical men allow themselves to be exploited. Members of the profession who allow themselves thus to be used are not only short-sighted in their own interests, but are betraying the rights of their colleagues.

#### CURRENT TOPICS.

## The Increase of the "Conscientious Objector" to Vaccination. When Mr. Balfour's "conscientious objector"

came into existence it was fairly evident that the species would increase and multiply when blind mothers and ignorant fathers began to comprehend the possibilities of the situation. It is so much easier for most of us to run the risk of a remote contingency like small-pox than to face the visible discomfort of vaccination. Accordingly, it is not surprising to learn, on the authority of the Northern Echo, that in the Amble and Raafe townships of the Alnwick Union there is a strong increase in the number of "conscientious objectors" to vaccination. By the return of Mr. Taylor, vaccination officer, it was shown that while there were 20 in one half of 1907, the number had increased to 147 in the corresponding half-year of 1908. When this statement was laid before the Alnwick Guardians at their ordinary meeting, one of the members remarked that a visit of small-pox would tell a sad His prophecy might have hailed from any responsible medical authority, so obvious is the scientific soundness of his surmise.

The Danger of Old Prescriptions.

The risks attendant on the use of old prescriptions are known to most medical men. Some patients not only use physic that has been ordered for them several years previously—possibly for essentially differing pathological conditions—but they go the length of hawking their prescriptions among friends——relatives. Instances have been known

in which the prescriptions of some famous surgeon or physician have been handed down as valuable heirlooms from father to son. The risk of a patient using an old prescription for the purpose of obtaining a poisonous drug is not generally recognised by members of the medical profession. A case in point occurred recently at the City of London Coroner's Court. An Italian restaurant-keeper committed suicide by means of corrosive sublimate which had been medically prescribed for him to be used as a lotion some years previously. On the strength of the prescription he obtained a bottle containing twenty-five tabloids of the drug. The Coroner pointed out that the new Pharmacy Act did not meet all difficulties. It was shown in evidence that medical men were not required to place the word "poison" on prescriptions containing deadly drugs. The chemist who dispensed the corrosive sublimate pointed out a precaution adopted by some medical men, who marked their prescription, "not to be dispensed" after a certain date. This point is worthy of careful consideration by all practitioners who are called upon to prescribe remedies, poisonous or otherwise.

Deaths by Poison.

THE Annual Report for 1907 of the Registrar-General for England gives some interesting figures regarding deaths by poison in that year. The number of accidental deaths due to poisoning was 248, as against 245 in the previous year. Of these poisons, opium, including its derivatives, was most frequently at fault, causing 70 deaths. Next to it came hydrochloric acid, which caused 17, and then ammonia 16, and carbolic acid 13. Of the less common poisons, mushrooms caused 7 deaths, poisonous berries 1, and the sting of insects 2. In addition, there were 109 accidental deaths due to poisonous vapours. Of these coal-gas came first with 51 deaths, and carbon monoxide next with 14. Of 186 deaths due to anæsthetics, chloroform caused 95, ether 10, chloroform and ether 5, nitrous oxide 3, A.C.E. mixture and ethyl chloride 2 each; the kind of anæsthetic was not stated in 69 cases. We are probably right in thinking that chloroform was responsible in most of them. Its extraordinary preponderance over ether is therefore well shown. The number of suicides by poison during the year was 530. Apparently the guiding factor in the choice of a poison was ease in obtaining it, for the three substances most often employed were carbolic acid in 93 cases, hydrochloric acid in 83, and oxalic acid in 81, substances commonly used in the arts or for household purposes. Other poisons frequently selected were opium in 60 cases, hydrocyanic acid in 33, potassium cyanide in 30, ammonia in 15, and strychnine in 13. Coal-tar was used in 1, and yew leaves in 1. In addition, coal gas was used by suicides in 63 cases, and carbon monoxide in 2. In 3 murders poisons were employed, hydrocyanic acid in 2, laudanum in 1.

#### "Reasonable Skill."

A somewhat curious civil action has been recently tried at the Sussex Assizes. It was brought against a country practitioner for damages for alleged negligence in his attendance on a lady patient. From the evidence it seems that an error

of diagnosis was committed by the defendant as regards pregnancy, and that on his account being presented legal action was taken against him, A large amount of expert evidence was brought to show that the defendant had not shown undue negligence, although it appears to have been admitted that he had omitted to use a stethoscope. The case was exhaustively dealt with, and ended in a verdict in favour of the defendant. The judge, in summing up, said what the female plaintiff was entitled to from the defendant was such care and skill as was reasonable or ordinary in the profession, and to an extent they must put aside his qualifications, because a man might be brilliantly qualified, and yet be negligent. We were all wanting in perfection in knowledge, even lawyers, and it did not follow that because defendant was brilliantly qualified he might not have been off-handed. The jury must be absolutely sure plaintiffs had made out their case before they could find in their favour. If they had a doubt, or anything short of positive certainty, the defendant was entitled to their verdict. A better appreciation of the proviso of "reasonable skill," as emphasised by his lordship, would prevent many a foolish and vexations lawsuit.

#### The Report of the Poor-Law Commission.

THE Commission on the Poor-laws and Relief of Distress considered it expedient to deal with Ireland and Scotland in separate reports, which have not as yet been issued. A forecast of their recommendations has, however, already appeared, which enables one to form a fairly definite idea of the character of the Report itself. The Commissioners state that at the outset of their inquiry they found a Viceregal Commission had lately reported on several points in connection with Poor-law administration in Ireland, and had formulated certain proposals. The Commissioners considered they were greatly indebted to this report, so much so that, while they visited Ireland to see the state of affairs with their own eyes, they did not consider it necessary to call fresh evidence. The scheme recommended by the Commissioners falls in with the view of the Viceregal Commission in the main, save as regards their proposals affecting outdoor relief and the retention of the old boards of guardians. From this it appears that the Commission will recommend the creation of a State medical service, and there will be a real prospect of the abolition of some of the worst abuses which accompany the present position of affairs, both in regard to the appointment of medical men to the service and the treatment of them when appointed. The Government can hardly shut their eyes any longer to the existing state of things or shelve the recommendations of two Commissions, and it is gratifying to learn from the lips of the Premier that "the supporters of Poor-law reform in Ireland need have no apprehension that the recommendations of the Viceregal Commission would be ignored."

#### PERSONAL.

On the 22nd ult., the Princess of Wales opened a new children's ward at the Great Northern Central Hospital in Holloway Road, London.

MR. P. A. NAIRNE, Chairman of the Committee of the Seamen's Hospital, presided last week at the first annual dinner of the London School of Clinical Medicine, held at the Savoy Hotel. Dr. W. G. SARGENT has been appointed a magistrate for the County of Monmouth.

Dr. A. F. L. Dorin has been elected President of the Metropolitan Police Surgeons' Association.

THE Gillson Scholarship in Pathology (1909) of the Society of Apothecaries of London, has been awarded to Philip Noel Panton, M.B. (Camb.).

CAPTAIN HAYWARH PINCH, F.R.C.S., Medical Superintendent of the Polyclinic, has been appointed Director of the new Radium Institute.

The name of Sir Thomas Barlow, Bart., M.D., is among those of the candidates recommended by the Council of the Royal Society for election to the Fellowship of that body.

Dr. Hugh Woods and Sir William Sinclair, M.D., gave evidence last week before the Departmental Committee of the Privy Council sitting to inquire into the working of the Midwives Act.

It is proposed to make a public subscription to present Dr. E. M. Grace, the veteran cricketer, with a testimonial on his resignation, after 40 years' service, of the post of Secretary to the Gloucestershire County Cricket Club.

MR. GILBERT BARLING has been placed on the Commission of Peace for Birmingham. He is Dean of the Faculty of Medicine at the Birmingham University, and Hon. Surgeon at the General Hospital.

Dr. R. S. Simon, Honorary Physician to the Birmingham General Hospital, has been appointed a J.P. for that city. He is cousin to the Prime Minister, whom he has entertained on each occasion that he has visited Birmingham.

MR. J. LENTAIGNE, President of the Royal College of Surgeons of Ireland, took the chair at the annual dinner of that institution on February 20th. The Lord-Lieutonant honoured the company with his presence.

A PROVINCIAL sessional meeting of the Royal Sanitary Institute will be held on March 12th and 13th at Sheffield. A discussion on "Medical Inspection—Its Relationship to the Home Life of the Children," will be opened by Dr. Ralph P. Williams, Assistant Medical Officer of Health, Sheffield.

LAST week Sir William J. Collins asked, in the House of Commons, whether any steps were to be taken with regard to "kissing the book" in the administration of oaths, and was answered by Mr. Herbert Gladstone that the matter was under consideration, now that infection had clearly been traced to that source.

Dr. Hebert, of London, has been awarded several hundreds of pounds damages against the Morning Leader, Star, Weekly Despatch and other newspapers, by way of damages for a libel stating him to have been connected with a bogus matrimonial agency in Paris. Apologies for repeating the libel have been published by a large number of journals.

SIR RUBERT BOYCE, F.R.S., Dean of the Liverpool School of Tropical Medicine, has been asked by the Colonial Office to visit the West Indies with a view to instituting reforms in the hygienic methods in practice in those islands. He is expected to arrive at Barbadoes this week.

The International Congress of Ophthalmology will meet at Naples from April 2nd to April 7th next, and not from March 2nd as was inadvertently stated in our last issue. Corresponding secretaries in the United Kingdom are Mr. Walter Jessop, London; Dr. George Mackay, Edinburgh; and Sir Henry Swanzy, Dublin.

#### A CLINICAL LECTURE

ON

#### THE PRESENT POSITION OF INTRAVENOUS TREATMENT.

By FELIX MENDEL, M.D.,

Essen (Ruhr).

[SPECIALLY REPORTED FOR THIS JOURNAL.]

PART I.

THE endovenous application of medicines has gained such a considerable importance in practical medicine during the last ten years that we must presume that every physician has a proper knowledge of the numerous indications for this method of treatment, and that he has enough dexterity to be able to make use of it secundem artem. It required a long time and manifold experiences to overcome the dread of intravenous therapeutics that long prevailed amongst medical men, although it has been firmly established for years that all the objections against this method of medication that have been brought forward again and again, and that it is dangerous in practice, have no scientific and practical basis. It has been fear of air embolism that even to the present day has kept back the majority of physicians from making use of Then, also, with the development of bacteriology and the doctrine of anti- and asepsis, came the fear that an injection not perfectly aseptic might set up a general section and personal section are general section as personal section and guarantity of air, even when it penetrates into a vein, To-day we know that a small which, however, can be easily avoided, is absolutely free from danger to the circulation. There is, therefore, no fear of air embolism, or it can be excluded

with absolute certainty.

Septic infection is still less to be feared in our method of treatment, for the operation is so simple and slight that it can be performed aseptically even without much attention. Then we have also learned that when, even in spite of care, a few micro-organisms find entrance into the blood-channels, they are easily made innocuous and removed from the system by the bacteriolytic and anti-toxic properties of the blood, when they might be dangerous if admitted by subcutaneous injection, as they would then have the opportunity of settling in the tissues and forming centres of suppuration, which would constantly be sending fresh infective material into the system. On these grounds we are in a position to formulate the following—contrary to the views hitherto current—that, cateris paribus, a subcutaneous injection can be more dangerous to the recipient than an intravenous one.

A striking proof of the correctness of these deductions is furnished by the fact that, in spite of its manifold employment, not a single case of general infection and fatal embolism has been reported after the intravenous application of medicines, an experience that I can fully confirm after thousands of intravenous injections of my own. Of course, proper selection of the medicaments to be made use of is of great importance, and also a specially cautious dosage, along with careful consideration of their pharmacological properties. Medicines that can be used intravenously without danger, and so avoid any local and general mischief, and, above all, thromboses and emboli, must have the three following properties:—

(1) They must not set up any coagulation of the fluids of the blood.

(2) They must not in any way injure the corpuscular elements of the blood.

(3) They must not injuriously interfere with the normal function of the endothelium of the veins, as only a healthy vein wall can prevent the formation of thrombi.

It will naturally also be understood that all medicaments are to be excluded from intravenous injection that may choke the capillaries either by their consistence, their aggregate constitution, or admixture of bodily elements.

If a medicament fulfils these conditions, the intra-

venous administration of it may be said to be free from danger, apart from its pharmacological and dynamic properties; it therefore possesses great advantages over all other kinds of medication.

In the case of internal administration the medicines undergo so many changes during the progress of digestion, before they reach the circulation and begin their work, and are so often so imperfectly absorbed owing to the condition of the digestive tract, that the dose actually taking effect cannot be calculated beforehand, and it does not enter into action either quickly or with certainty. Then we must take into consideration a direct injury to the digestion by the medicine, an evil that not only has a bad effect on the general condition of the patient, but not infrequently retards the absorption of the drug, and makes it impossible to carry out the treatment by internal means.

From this point of view subcutaneous and intramuscular injections are a distinct advance, in contrast to internal administration, and in many cases they may even take the place of intravenous infusion.

But there are a number of substances that, if injected subcutaneously or into the muscles, set up such strong symptoms of local inflammation as to make their employment not only difficult, but it altogether delays or prevents their absorption. As such substances are in many cases suitable for intravenous injection, this, if we do not go back to administration by the mouth, is the only way possible.

With intravenous injection the medicine at a stroke both gets into the blood current and in full dose, where it may act with much more energy than by any other mode of administration. The experiences of the last ten years prove this, and the most recent experiments fully confirm it. The theoretical objection that this energetic action is of only a short duration, and that the rapid entrance into the blood channels necessitates a rapid expulsion, has been shown to be unfounded, since my own searching experiments (Felix Mendel, Therapie d. Gegenwart, 1908, July) on the excretion of medicines administered through the veins, especially sodium salicylate and potassic iodide, have determined that the intravenous injection of medicines rather retards than accelerates their excretion, that therefore the strikingly heightened therapeutical effect depends on the combined effect of two components, on the simultaneous entrance of the full dose of the medicine into the blood tract and its retarded elimination. But all objections that have been raised over and over again against intravenous treatment, and have stood in the way of its spread, are refuted in an especially thorough manner by the historical development of our method of treatment.

The direct infusion of medicines into the blood tract was already made use of in the first half of the last century—that is, long before the teachings of antisepsis had robbed our operative measures of the greatest part of their terrors—frequently with good success, especially in such diseases as threatened life, where the act of swallowing was prevented by spasm or unconsciousness on the part of the patient, and nucdicines could not be got into the system in any other way. In such cases, along with the unavoidable venesection, the intravenous injection of tartarised antimony and other emetics played an important part, and often had a life-saving effect, judging from the accounts given of the cases. But a number of other medicinal substances were also given in the way of infusion, such as the narcotics, belladonna, opium, morphia, chloral. Yea, even the insoluble camphor, mucilage, atmospheric air—things that with our pre-

sent physiological knowledge we should scarcely dare to make use of. But the names of those physicians that made use of these drugs, and their recognised capabilities as observers, are a sufficient guarantee that this method of giving medicines had no dangerous consequences as regarded the patient. From the imperfect instrumentarium of the time, the infusionto-day so simple-must have been a serious surgical undertaking. The wound rarely healed without sup-puration, and even in the most favourable cases led to ulceration in the neighbourhood.

A greater part of the indications for intravenous treatment disappeared with the introduction of the Pravaz syringe (1853), which rendered possible the simple subcutaneous injection of medicines, instead of a complicated operation that could only be performed by an expert. In this way intravenous treatment gradually fell away into forgetfulness, and for decenniums it was scarcely ever practised, until the animal experiments of Kronecker and Sander, who saved dogs from certain bleeding to death by intravenous injection of physiological saline solution, which prompted Landerer to try this method of treatment, not only in cases of acute anæmia, but to give other medicines by way of intravenous injection.

There may be a divided opinion regarding Landerer's (1895) so hardily contested intravenous injection of hetol, but the services of that inquirer are incontestable in restoring the endovenous application of remedies that were well-nigh forgotten, and making

the common property of the profession.

Considerable impulse and vitality was given to intravenous treatment by Baccelli, especially by his works on the intravenous administration of quinine and sublimate, which gave an impetus to a new and brilliant development of this method of treatment. In 1907 Crede introduced intravenous silver treatment by collargol. In the same year Herxheimer introduced the intravenous injection of arsenious acid, which ranks along with the intravenous injection of sodium cacodylate introduced by myself in 1902-3 An iron combination with cacodylic acid (ferricodyle) has been given by venous injection in place of the internal administration of Franck (1966). As, however, sodium caco-dylate, in consequence of its ready decomposition, seemed less suited for intravenous injection than a new organic preparation of arsenic, atoxyl, in carrying out intravenous arsenical treatment I have given preference to it. As early as 1901 Robert Koch had ascertained by experiments on the human subject that tubercle bacilli (and especially T.O.) had the property, even in small doses, of raising the agglutinating power of human serum against tubercle bacilli to a surprising degree, and that they showed themselves active even when no effect was produced by subcutoneous injection, although the dose was increased. This observation of Koch's justified the certain expec-tation that the "alttuberculin" also injected direct into the vein would exert a considerably more powerful bactericide action. For this reason the intravenous injection of "alttuberculin" alone and in combination with atoxyl was recommended by me, and by this the impulse was given for the employment of other bacterial products for the purpose of accelerating or increasing their action, as proposed by Lehmann (1904) with regard to the intravenous injection of Behring's curative serum in bad cases of diphtheria.

In 1904 the intravenous injection of salicylic acid was introduced by me, and simultaneously with this specific remedy, caffeine, which opened the way for the alkaloids, which are specially suitable for intravenous injection, and, even as long as ten years ago, were many times introduced directly into the blood

current (morphia, strychnine, etc.).

With the intravenous injection of caffeine, introduced by me (caffeine sod. sal. 1:10), which gave us the power of at once increasing the power of the heart from the blood current, properly begins a series of important experiments to prepare remedies for the heart, and especially digitalis for intravenous injection. This must appear the more important, as this indispensable and active cardiac stimulant frequently offers the greatest difficulties, both as regards internal and subcutaneous administration, and its action, as at present incorporated, is too slow to afford relief in time when the indication for it is a vital one. In 1905 Kottmann introduced digitoxinum solubile Cloetta (digalen) into intravenous therapeutics, and simultaneously and independently of these investigations digitalonea digitalis dialysate, a preparation of the firm of Parke, Davis, and Co., was recommended by me for intravenous medication. After the attempt of myself and Kottmann to introduce cardiac remedies by way of intravenous injection had once been successfully made, Fraenkel, from his intimate knowledge of the digitalis bodies, ventured to introduce direct into the venous blood channel a much more rapidly and even heroically acting remedy of this group-strophanthin (Böhringer), a remedy that Baccelli had made use of independently of Fraenkel in paroxysmal tachycardia with a brilliant effect.

Ample experience has shown that intravenous digitalis treatment, whether caffein, digalen, digitalone, or strophanthin, be made use of, is an important advance

in the treatment of cardiac cases.

Adrenalin-saline solution, first recommended by Heidenhain, which often has a life-saving effect in diminished intraperitoneal blood pressure, serves a similar purpose.

In recognising that the treatment of infectious diseases must form the real domain of intravenous therapeutics, and as atoxyl has been recognised as a specific against the so-called protozoa diseases, I pleaded urgently for its employment both in sleeping sickness and in malaria. Von Döevenspeck has recommended the intravenous employment of potassic iodide in bad cases of syphilis, whilst the intravenous injection of quinine of Lehmann may be mentioned as the most recent achievement in this direction.

Even if the injection of potassic iodide and colchicin iodide, with attendant success, has up to the present gained no practical importance, and the intravenous infusion of oxygen has, so far as I know, only been employed in the case of animals, we see from the above that the most important remedies are eminently suited for intravenous injection free from all disturbing by-effects, and develop their curative action in a prominent manner. From our present experience we may make the formal pronouncement that intravenous therapeutics, with a suitable selection of remedies, and skilfully carried out, is free from any local or general injury to the patient.

If, in spite of this, intravenous treatment has remained a terra incognita, full of terror, and one that the ordinary practitioner dare not venture upon, is due to the fact that, up to quite recently, there was no klinik in which this mode of administering remedies was taught, and because University circles especially held aloof from this form of treatment. On the other hand, I have often seen that medical men who have had the opportunity of seeing the simplicity of the proceeding themselves, and the brilliant results of the picceding themselves, and in ordinal testing following it, have become enthusiastic admirers.

The technique of intravenous injection is exceedingly

simple, and may be carried out easily and without danger, as well in the consulting-room as at the bedside. Although during the course of years proposals of improvements have been made by various authors, both in regard to the instrumentarium and the technique, I have found no occasion to deviate from that first described, and fully tested except in one particular.

The apparatus that the firm of J. and H. Lieberg, of Cassel, made from my instructions, and supplied in a very handy case, consists of a band of black indiarubber 6 cm. in width and about 1 metre in length, and a Lieberg 2 gm. syringe, with a not too fine platinum-iridium needle. In the Lieberg case are two needles in a metallic cover, in which they can at the same time be sterilised. There is also in the case an ether bottle with an ingenious stopper, and room for the ampullæ, with the medicines.

After the cannula has been boiled in water, and the needle which is to be used has been washed, and some of the same water passed through, it is filled with the medicine, the needle fixed firmly, and the air driven out of both syringe and needle. The veins at the flexure of the elbow are then closed by the elastic ligature, and the point of puncture rubbed with sulphuric

That vein is to be selected for puncture that ether. seems to the touch to be the most tense and adherent to the skin, so that the needle, on entering, cannot slip aside. Then the cannula, firmly fixed on the syringe, is passed straight in, and when we see the column of blood mounting in the cannula and syringe, forced there by the strong pressure on the contents of the vein, and are assured thereby that the cannula is really in the lumen of the vein, or when we have satisfied ourselves that it is by drawing slightly on the piston, slowly and under equable pressure the contents of the syringe are passed into the vein. After the cannula has been withdrawn, and a pledget of gauze placed on the site of the puncture, the bandage is taken off. Many loosen the ligature, or allow the patient to do so, before emptying the syringe, as soon as the cannula has entered the lumen of the vein. This method has the advantage that the medicine at once pours into the open channel of the vein, and in this way any lengthened contact of the drug with the wall of the vein is avoided. We must act in this way when large quantities of fluid are to be injected at once. It has, however, the disadvantage of uncertainty, as, after loosing the ligature, the needle may easily get displaced by movements of

By my method I have often made 50 and more injections in the same spot of the same vein, without being able to detect the slightest trace of irritation or thrombus. For any damage to the intima of the vein and the formation of thrombus due to it, the character of the fluid injected is responsible. It is injurious to the vein and disagreeable to the patient when some of the fluid to be injected, instead of going into the vein, gets into the perivenous tissue, as it is the property of most intravenous medicaments to set up painful inflammations and infiltrations, and as a consequence of these venous thromboses it is advisable to carry out intravenous injections only with medicines which are sterilised in individual doses, and preserved in ampullæ, with their necks closed by melting of the glass, and in this way be sure that the material is free from germs and decomposition. Such ampullæ are mostly prepared in the factories and kept in stock in drug vendors' shops.

With the extensive range of employment of intravenous medication, and its great activity in numerous cases of illness, it seems proper to discuss the methods of treatment that are of the greatest practical import ance, their indications, as well as the exact mode of action and dosage of the materials to be employed.

(1) Treatment by Hetol (Landerer).

After Landerer had recognised Peruvian balsam and its derivatives, and especially cinnamomic acid, as excellent anti-tuberculous external applications, he attempted their employment in internal tuberculosis, first the balsam of Peru and the cinnamomic acid. As, however, the intravenous use of these preparations proved to be harmless only with the greatest caution, and in most cases were followed by injurious byeffects, the general employment of this treatment only became possible when, in place of cinnamomic acid, a 1 to 6 per cent. aqueous solution of cinnamomate of soda (hetol) was introduced by Landerer, as an intravenous injection in the treatment of tuberculosis. This remedy, just like cinnamomic acid, is said to form an inflammatory wall, consisting of round cells, a pneumonia-like process, round the tubercles, which have but little tendency to cicatrise. From the round cells of this inflammatory area a growth of connective tissue takes place through the diseased centre, causing gradual contraction of it, healing, and cicatrisation. Most authors have been able to determine that a strong lymphocytosis takes place, which is looked upon by Landerer as an important curative factor in the treatment of tuberculosis.

The method of treatment by hetol is the following:— The cinnamomic treatment should begin with the smallest doses (1 mgm. of hetol), and this can be gradually raised to the average dose proper to each case, but 25 mgm. must be considered the maximum dose.

Hetol treatment should set up no increase of fever, neither should it in any way be injurious to the general condition; in case it does, the dose must be reduced, or the treatment stopped altogether. Generally speak-

ing, one should try to get along with the smallest possible doses, and to be especially careful of the dosage when there is a tendency to hæmorrhage. The duration of the period of treatment varies from thirty days to three months.

In Landerer's opinion, we have in cinnamomic acid and its derivatives a remedy that has a powerful influence in tuberculosis, the intravenous injection of which is absolutely harmless, and which, in a considerable proportion of those suffering from internal tuberculosis, and especially in cases without fever, and free from considerable disturbances, will bring about absolute or comparative recovery in the course of a few months.

This treatment, inaugurated by Landerer, has been tested a good deal quite recently. All authors are agreed on one point—that the treatment does no harm, whilst favourable reports on the success of the method are opposed by a number of others, which make this success questionable, and, judging from the most recent experiments on animals, no action on tuberculosis can be ascribed to it.

(2) Intravenous Treatment by Silver (Credé).

Credé attempted to make use of the highly antiseptic properties of silver by introducing it in a soluble form, in which it caused no precipitation in the blood fluids, and only passed away from the blood-vessels very slowly. Collargol (argentum colloidale) is supposed to possess such properties, and, for this reason, to be peculiarly suited for introducing into the blood, and the whole body, a solution of silver.

The intravenous injection of 1 to 5 ccm. of a 5 per cent. solution is acknowledged by all authors to be quite harmless. It is borne by the walls of the veins without any irritation, as there is no local reaction, and the dose may be repeated in 24 hours. Along with the percutaneous incorporation of collargol by means Credé's ointment, he recommends intravenous injection, especially in cases in which a prompt effect is desirable, or where from any cause-disease of the skin, cachexia, or age—there is not likely to be suffi-cient absorption through the cutaneous tissues, in all cases of septic infection of any kind, and whatever the cause may have been. In the whole of the cases even in those that appeared hopeless by any other method of treatment-rapid improvement is said to have set in, even in a few hours' time, as shown by improvement of the general condition, rapid fall of fever, and retrogression of the septic process. An extensive list of cases goes to show the great value of this form of treatment through the whole domain of septic infections (sepsis, pyæmia, erysipelas, angina, diphtheria, pneumonia, febrile tuberculosis, gonorrhœal articular diseases, etc.). Opposed to this is a series of writers who, as well by experiments on animals as by their own experiences at the bedside, seek to prove that collargol is not only absolutely inactive, but must be so from the slight bactericide power of the material injected.

The question of the value of collargol treatment is therefore uncertain at present, and it will require a long time to accumulate a sufficient number of observations to decide the question of its value. In my own opinion this is the more difficult, as the septic diseases run so varying a course, and even in their severest forms not unfrequently may take such spontaneous sudden turns for the better that it must often seem impossible to weigh the post hoc and the propter hoc against each other with any degree of certainty.

(3) Intravenous Arsenical Treatment (F. Mendel).

(3) Intravenous Arsenical Treatment (F. Mendel). As the disagreeable by-effects of this old and well-tried remedy have stood in the way of its employment in sufficiently large doses and for sufficiently long periods, pharmacologists have for a long time been seeking for a substitute for arsenious acid which, without injuring the gastro-intestinal canal and causing various symptoms of intoxication, may be given for lengthened periods and in efficient doses. As such a preparation of arsenic atoxyl was introduced into therapeutical use by Schild and Blumenthal in the year 1902, and its intravenous injection in 20 per cent-solution was recommended.

From its employment in a large number of cases I have given the preference to a 15 per cent. solution, in order by this means to get not only a more efficient

smallest trace of the treatment.

ORIGINAL PAPERS.

THE MEDICAL INSPECTION OF SCHOOL CHILDREN.

By H. O. PILKINGTON, M.D., D.P.H.,

Medical Officer of Health for Preston.

Treatment by intravenous injection of atoxyl is begun by one-third of a gramme of a 15 per cent. solution of atoxyl, gradually increasing the dose to 2 gm.equal to 0.3, which I consider as the maximum dose. The injection is repeated every second day generally for four weeks, then twice a week, then once a week, to the end of the course. Atoxyl is used in all the ciseases in which arsenic appears to be indicated. The results, from the absence of by-effects and the relative harmlessness of the preparation, may be said to be brilliant in comparison with the preparations hitherto

action, but also absolute paintessness of application. For subcutaneous injection, in spite of the most careful asepsis, it not infrequently causes considerable irritation far beyond the site of the injection, whilst a

15 per cent. solution poured into the vein is so non-

irritant that 50 injections and more may be made at the same spot in the vein, without leaving behind the

This method of arsenical treatment proved itself very effective in the most diverse disturbances of blood formation (chlorosis, anæmia, leukæmia), in nerve diseases of the most varied kinds (neurasthenia, hysteria, nervous asthma, paralyses, neuritis, chorea, etc.); also in Basedow's disease, diseases of the skin, glandular swellings, pseudo-leukæmia

The intravenous employment of atoxyl in tuberculosis deserves special notice, as it is just in this disease, associated as it is with loss of general power, that it shows most clearly the favourable influence that arsenic in this form has over the general processes of nutrition. It is in tuberculosis that atoxyl proves itself to be an excellent remedy for raising the lowered vitality of the cells and increasing their power of resistance against the tuberculous poison.

Atoxvl has gained distinguished importance in the treatment of tuberculosis, but it did so first through my introduction of the intravenous employment of atoxyl and tuberculin for that disease, which, as I should like to mention, showed the best results in the out-patient treatment of the first and second stages of the disease. In this combined arsenic-tuberculin treatment, the procedure is so that to the increasing dose of the arsenic, if the case calls for it, an increasing dose of tuberculin is added in such a way that the syringe containing the arsenic is made to take up so many parts of a 1 to 1,000 solution of tuberculin as will make an injection of a decimilligramme of tuberculin.

By the intravenous injection of these two substances, a bacterial product and a chemical substance, we first of all succeed in multiplying many times over the specific action of the tuberculin, as shown by Koch's experiments. At the same time, an inflammatory hyperæmic zone is formed around the tuberculous centre from the local reaction of the tuberculin, the result of which is the formation of a reserve of the arsenic circulating in the blood, and with it an increased curative effect in the cell territories that are the most endangered.

The tuberculin thus forms, to make use of Ehrlich's expression, the loaded waggon, carrying the burden entrusted to it—the arsenic; passes it on to the parts most in danger; at the same time it develops within the organism in a high degree a protective power against the virus of the tubercle, whilst the arsenic, along with its increased local curative effect on the diseased parts, exercises a general tonic effect. combined arsenic-tuberculin treatment, fulfils all the requirements which Ehrlich has called for in the ideal remedy, as it allows the various factors to come into action, the coming together of which first renders a curative effect possible—(1) the distributive constituent parts regulating the dissemination (tuber-culin); (2) the pharmacophore group (as + tuberculin), rendering a specific action possible.

NOTE.—A Clinical Lecture by a well-known teacher eppears in each number of this journal. The lecture for next week will be by Felix Mendel, M.D., Essen (Ruhr.). Subject: "The Present Position of Intravenous Treatment." -Part II.

By Section 13 of the Education (Administrative Provisions) Act, 1907, a duty is cast upon a Local Educa-tion Authority of providing for the medical inspection of all children entering a public elementary school, such inspection to be made immediately before, at the time of, or as soon as possible after, the admission of each child.

In addition, an inspection shall be made of each child on such other occasions during its school life as the Board of Education may direct, and the present direction is that the inspection upon admission shall be followed by another about the third year of school life, and again by another about the sixth year. recommended that a still further inspection shall be made when the child leaves school and commences some form of employment, and in some districts it is considered possible that this final examination may with advantage take the place of the third, that in the sixth year of school life. This Act came into force in January of the present year, but it was quite recognised that such an important undertaking could not be got into steady, regular working order without a great deal of preliminary trouble and careful consideration, and therefore it is not expected that a Local Authority can do much more than examine the entries made during the first year.

A recent Memorandum explains that the Board will be satisfied, so far as the present year is concerned, by the inspection of all children entering after August 1st, and those who are likely to leave before

or about July, 1909.

The Board recognise that such an important work as this cannot be commenced, and certainly cannot be got into smooth working order, without a good deal of discussion, of preliminary trial, and of

gradually acquired experience.

Undoubtedly, this Act requiring the medical examination of school children is one of the most important, and, it is to be hoped, will prove one of the most beneficial, of recent years. It is the outcome of a feeling that amongst the children now growing up there is, if not an actual physical degeneration, at any rate a falling-off from the standard which might naturally be expected.

There is already evidence—and this will be confirmed by the inspections now going on—that many children are suffering from ailments, and from physical disabilities, which are either altogether unrecognised, or else are treated as matters of no importance, or as conditions which time may cure, and which must be left to chance, good fortune, or Providence. In this way men and women have grown up, and are now suffering from defects which, if only recognised and judiciously treated during their school-going age, might have been materially relieved, if not altogether cured. Every child, and more especially children of the working classes, enters upon the struggle of life heavily handicapped if it has not full possession and use of all its limbs, senses and faculties.

Few people fully appreciate the heritage of a sound constitution, and the blessing of having a fair start in that race in which the cripple must needs lag behind; a fair chance in that struggle in which the weakest must almost invariably go to the wall.

is the object of a medical inspection This, then, of school children—to detect abnormal conditions whilst still they may be improved, weak spots, which now, perhaps, of little importance, may, if left untreated, develop into serious ailments, and conditions which may perhaps have no very serious influence on the health of the child, but which indicate negligence and want of proper care on the part of parents and guardians.

It is evident that the medical inspection of a child is intended to be the means of detecting some unnatural condition, and is but the first step-but an absolutely necessary one—towards its amelioration or cure.

Since this inspection of children is but another form of Public Health work, it has been decided that it must come under the supervision and control of the Health Officer for borough, township, district, etc.

The course adopted in Preston may be taken as a

The course adopted in Preston may be taken as a type of that which has been carried out in most of the large towns. The Medical Officer of Health is supervising officer, but since it is evident that his other multifarious duties will prevent his acting as actual inspecting officer, a fully qualified medical man has been appointed, upon whom will devolve the actual and responsible work of inspection. But, in order that this work of inspection may be carried out in the most efficient, and, so far as time is concerned, in the most efficient, and, so far as time is concerned, in the most efficient, and, so far as time is concerned, in the most efficient, and, so far as time is concerned, in the most efficient, and to operation of the teachers should also be obtained. It is of primary importance that they, who have so much to do with the well-being of the school and of the school children, should take an interest in the work, should see that it is intended to benefit the children under their care, and that the increased labour which may and will be thrown upon their hands is likely to bear good fruit in the improved health, and future happiness and success of the children over whom they are placed in charge.

This interest once aroused, this co-operation once secured, much of the difficulty which must surround the inception and inauguration of an important measure like this, is at once overcome.

For some years past in Preston, as in many other large towns, there has been a relationship between the Education and Public Health Departments, working for the good of the school children. All cases of minor infectious disease—those not compulsorily notifiable under the Infectious Diseases Notification Act—as, for instance, measles, whooping-cough, mumps, chicken-pox, ringworm, and various skin eruptions, occurring amongst the children of a school, are reported to the Health Office by the teacher.

These cases are attended to by the Health Visitors, who give advice (carefully avoiding any opinion if a medical man be in attendance), upon the need for isolation, and see that the proper period of quarantine is observed. In the same way, the Health Office supplies the teachers with information of those houses in which cases of the more serious forms of infectious disease are reported to have occurred, and so enables them to prevent children from these infected houses attending school until the period of danger has passed and the house and contents have been disinfected.

It is here that, under the present Education Act, the services of Health Visitors may be further utilised. The Medical Inspector of School Children cannot himself visit them at home, or see that the advice which he may give is properly carried out.

Such a course might bring him into conflict with the private practitioner, the medical adviser of the family, and this is a point which by all means must be avoided. But notice of suitable cases sent to the Health Office will ensure the services of the Health Visitor, and the Education Authority recognise the importance, and, indeed, the necessity, of the co-operation of school nurses, or Health Visitors, who will serve as a connecting link between the school and home, will secure and maintain the personal cleanliness of the child, will see that medical advice is obtained in necessary cases, and stimulate the parents into a proper sense of their responsibilities.

Besides the actual detection of disease, want of cleanliness, etc., the Medical Inspector will be able to pick out those children who are either mentally defective, or who, on account of physical ailments, are unfitted to take their places amongst children of their own age, and for these he can suggest some modification of the system of education suited to the needs and capacities of such children. Children with pronounced deficiency of intellect, (idiots and low-grade imbeciles) should, of course, be withdrawn from an ordinary school. They are subversive of discipline, and to a certain extent are infective, since they spread demoralisation around them, and impede the educational advancement of the other children. For them treatment in some special institution is impera-

tive. But those who are defective in a minor degree, the simply backward children, should not be withdrawn from the general system of the school, or from contact with the other children, but should be subjected to some modified form of education, which will strengthen their weak points, and draw out—educate—what they have of the best. This is the opinion of Sir James Crichton-Browne, expressed very much in the words which he used when speaking on this subject at the recent annual dinner of the Society of Medical Officers of Health.

Now as to the actual manner in which the inspection of these school children is to be carried out.

It is required to be held on school premises and during the recognised hours of school work.

In making the necessary arrangements, the circumstances of the school must be taken into consideration, and also the convenience of the teaching staff, so that the routine work of the school may be as little as possible interfered with. If possible, a separate room should be obtained, so that the general body of scholars are not distracted from their lessons.

Certain apparatus and instruments are necessary, some being required in the case of every child examined, others only in those cases in which some defect is apparent, but all these are intended simply for examination, and not for curative purposes, these latter being outside the medical examiner's functions.

The particulars of the examination are first set down upon a card, ruled so as to show the various particulars during each of the four examinations required by the Act. First comes the child's name, date of birth, its address, and name of school which it is attending. Then its previous history, so far as to show any serious illness which is likely to have any effect upon its future health, also the family medical history, if there be anything exceptional to record. These are general items, which once recorded, need not again be dealt with. Then follow the personal conditions, as found on each inspection, divided under 24 headings. Date of inspection, standard and regularity of attendance, age, condition of clothing and foot-gear, height, weight (these may be taken in English measures, but in Annual Report averages must be given in English and metric systems), nutrition, cleanliness of skin, head, and body, and condition of teeth, nose and throat, tonsils, adenoids, glands, eye disease, vision R. and L., ear disease and hearing, speech, mental conditions, heart and circulation, lungs, nervous system, tuberculosis, rickets, deformities, spinal disease, infectious and contagious disease, other disease or defect, general observations. Then follow any directions which it may be necessary to give to the parent or teacher, for their guidance in dealing with any defect which may have been discovered. All the facts relating to the child are recorded on the card bearing its name, and are afterwards copied in a register, to be regarded as confidential and to be kept at the school. The cards are kept in cabinets, one for each school, and should the child remove to another school, the card will accompany it. The presence of the parent at the first examination is recommended, at any rate, the opportunity of being present should be afforded.

Now, it will be seen that this examination is a very

Now, it will be seen that this examination is a very comprehensive one, and covers a great deal of ground; at any rate, it covers the whole of the child's body.

If the assistance of the teachers can be obtained, a good deal of the first part can be done by them; the height and weight can be taken, the family history ascertained, the attendance recorded, etc., and the child can be prepared—as to its dress—for the doctor. The memorandum issued by the Board of Education states that—"The examination of each child need not, as a rule, occupy more than a few minutes." But it would be very difficult in a few minutes, under the most favourable circumstances, to examine into, and then record, all the particulars dealt with. The examination of the vision by means of Snellen's Test Types, at a distance of 20 ft. or 6 metres, alone takes up some little time. Of course, there will be a certain proportion of children, obviously normal and healthy, whose examination will occupy comparatively little time, and they will serve to leaven the lot, and re-

duce the average amount of time required. Children who give evidence of some abnormal condition, impaired hearing or sight, spinal weakness or curvature, adenoids or other nasal obstruction, diseases of respiration, of circulation, etc., will be marked out for a further and more searching examination, probably carried out in the medical department of the School Attendance Offices.

In this way few children, who are in any way ailing or defective, will escape observation, but the after treatment presents greater difficulties, or rather the very necessity for it shows how far the Act may be extended, and that in numerous instances the inspection of the child is but the preliminary step, and will have to be followed, where necessary, by treatment at the public expense. It is obviously absurd to point out that a child is suffering from spinal weakness, or defective vision, if the parents are too poor or too apathetic to obtain the necessary treatment. Take the case of the teeth alone, which in the majority of the children are in a more or less decayed and carious condition. If not properly dealt with, they can only go from bad to worse, their condition being more than likely to exercise a baneful influence over the child's general health and development. And yet, amongst the labouring classes the teeth go through life untended and untouched, except when recourse is had to extraction to terminate the pain of an aching tooth, which, very possibly with proper attention, might still have been preserved.

extraction to terminate the pain of an aching tooth, which, very possibly with proper attention, might still have been preserved.

In seasons of prosperity and good trade, the difficulty will not be so great, but given a time of depression, of shortness of work, and scanty wages, and it will be found that the inspection of the child is but the first step towards providing for it. It would be little use recording that a child is insufficiently fed, imperfectly shod, and without sufficient clothing to keep it fairly warm, if it is known that these conditions, although fully recognised, cannot be relieved at home. There are, of course, many charities, and charitable institutions, and possibly arrangements may be made by which the requisite assistance, may wholly, or in part be obtained for those children whose parents are themselves unable to defray the cost. But these are matters which will have to be dealt with in the future, and the Act as yet has not been sufficiently long in operation to enable us to say how great will be the difficulties, or how best they may be avoided or overcome.

Instruction in the principles of hygiene, which teachers and intended teachers are now receiving, and which will be conveyed by them to the children under their charge, will do much to remove such evils as those arising from absolute ignorance of the structure and functions of the skin and teeth, and the consequent want of care in their treatment and preservation. The use of baths and tooth brushes, now forming in most schools a part of the curriculum, will not only be of direct and immediate benefit, but will also have an improving—a civilising—tendency; and will bring home to the rising generation the good effects resulting from personal hygiene.

Now, to the already sufficiently burthened rate-payer all this may seem but another step towards relieving a certain class of parents of the responsibilities which—as parents—must, and should, remain with them for the maintenance and up-bringing of their offspring. By some it will be said that all that such a parent need do is to produce the child, and the State will nurse it, vaccinate it, wash it, educate it, and, if necessary, feed and clothe it. It is, however, stated in the Memorandum issued by the Central Education Authority that "one of the objects of the new legislation is to stimulate a sense of duty in matters affecting health in the homes of the people, to enlist the best services and interest of the parents, and to educate their sense of responsibility for the personal hygiene of their children. The increased work undertaken by the State for the individual will mean that the parents have not to do less for themselves and their children, but more."

It is to be hoped that the parents in question will see matters in their proper light, and will, at any rate, exert themselves to co-operate with the Education and Health Authorities in their earnest endeavours to protect the health and improve the general condition of the poorer class of children in the town.

### BOOTS, AND THE TREATMENT OF CORNS AND PLANTAR WARTS. (a)

BY ALFRED EDDOWES, M.D.EDIN.

MR. PRESIDENT AND GENTLEMEN,—My attention was directed to this subject by a bad case of plantar warts which came under my care, and forcibly emphasised the practical importance of the malady. The patient, a young lady, had suffered some pain and inconvenience on the sole of the foot for two years; latterly all games had to be given up, walking was painful, and there was sometimes pain even in bed. A large number of such cases are going about constantly suffering, and are merely relieved a little now and then by chiropodists. The cases are essentially surgical, often easily curable in a week, may last a lifetime untreated, and are well worthy of careful study by those who are not already familiar with them. So much by way of introduction.

It must be understood that I shall make no attempt to deal with such a wide subject in a systematic and comprehensive way. I will merely enumerate some of the most important troubles which the feet are liable to, mainly from boots, and suggest means to lessen or remove them.

Blisters.—These usually occur on the instep, heel, sides and soles of the feet. Friction on the instep is usually caused by a badly-cut boot. A well-cut boot should have the line of lacing so cut that the front is smoothest and most closely adapted to the shape of the foot when we stand up. In this way the freest movement is allowed without unduly wrinkling the leather during extension or dorsi-flexion.

Blisters on the heels are usually caused by a boot slipping up and down with each step because the uppers are badly cut and do not take hold of the back of the heel. In other words, the line of the back part of the boot is too upright and straight, and does not recognise that the heel is more prominent than the tendo-Achillis. On the sole of the foot blisters are most commonly caused by roughness of the bed of the boot. Those forming at the side of the feet may be very extensive, and result from the sharply-bevelled edge of the bed of the boot, especially if the bed be too narrow.

Inflamed Nail-bed and Matrix.—The common causes of these very troublesome affections which bring about excessive thickness of nail-growth, if not actual deformity of the nail, are too short boots. with too little space in the toe of the boot, the last having been too short and too chisel-shaped. The result is well shown in an exaggerated form in the photograph I now pass round. There you will see about fifteen to twenty years' growth of the big toe nails both of which are turned upwards and backwards, and twisted like small rams' horns. These affections may have their origin in one definite injury, but more commonly they are due to wearing of too short boots, neglecting to cut the toe-nails, or from want of space in the toe or toe-cap of the boot, as has just been said. Most lasts make no allowance for the greater size of the big toe, so the roof of the vamp is not high enough.

In-grown Toe-nail.—This condition is at least greatly aggravated by short boots with too little space in the vamp, and too narrow a boot.

Bunion.—Bunion was much more common years ago when boots were more pointed in the toes and

<sup>(</sup>a) Read before the Chelsea Clinical Society, Feb. 16th, 1909.

spindle-shaped, that is to say, the line from heel to great toe was curved too soon and drove the big toe towards the centre of the foot.

Hammer-toc.-When this is acquired, as I believe is the rule, it is due to too narrow and too short

Flat-foot.-The ordinary flat-foot is greatly aggravated by the wearing of boots which are too unvielding, especially in the waist. Lacing firmly tends to drive the arch of the foot downwards upon the sole as if it were a ridged splint, and the extra strain thrown upon the arch of the foot tends, especially in cold weather, to excite severe cramps -generally coming on after getting into bed.

Morton's Disease, or transverse flat-foot, is an extremely painful malady when fully developed. It is, in my opinion, due largely to the cramping of the heads of the metatarsal bones in tight boots and boots which have too thin or too soft soles, which sometimes, when wet, will bulge downwards and encourage a corresponding bulging or descent of the heads of the second, third, or even the fourth

metatarsal bones.

Corns.-As we all know, corns are caused by over-stimulation of certain points on the foot through friction or intermittent pressure.

Warts of the feet may occur at any part, but it is only when they occur on the plantar surface that they are at all difficult to diagnose. They can be frequently distinctly traced to injury, plus, no doubt, various forms of infection.

Simple or infected wounds are of frequent occurrence owing to the scratching of the soles of the feet by badly-clinched nails or projecting wire sutures. I have known bits of wooden pegs, unremoved by the shoemaker, cause wounds.

SANDALS.

No one who realises that a boot can, and should be, so cut and formed as not to injure the feet would ever dream of recommending sandals for children, especially in our towns, where there is constant danger of infection of various kinds which

I need not specify.

Celluloid Heels .- Not satisfied with making dangerous inflammable combs, from which I have already seen terrible disasters, manufacturers, I am informed, now produce celluloid heels. Can any more horrible accident be imagined than might occur to a young lady coming home from a ball in an inflammable dress putting her feet near the fire, then suddenly finding the heel of her shoe blazing out into perhaps a cubic yard of flame, the result inevitably being death sooner or later, or a crippled condition for life. The result is too horrible to contemplate. The use of celluloid and other substances of such inflammable nature should be at once forbidden to form any part of boots, at least.

BOOTS. Having considered the chief faults of boots, let us see if we cannot lay down some definite and useful rules about the shape and make of a good boot. It should be easy, particularly for a soldier, to get his boots off and on quickly; therefore, in laced boots the opening should be as far down as the widest part of the foot, that is, a line running from the big joint of the great toe to the base of the little toc. The uppers should be so cut as to be smooth when the boot is laced and the wearer stands up in it. The back of the heel of a boot should receive the heel comfortably, and be so shaped as to prevent the foot working up and down during walking. There should be a little extra space about half an inch deep provided for by the shaping of the last-a little space which would correspond in position to that of a skirting-board

in a room-to prevent any cramping of the heel when it expands slightly backwards and outwards when pressed upon. If the space is not allowed, every step must fend to thrust the foot a little bit forward in the boot during every step. The bed of a boot, upon which usually lies a thin permanent leather sock, should be slightly cupped at the heel, slightly raised on the inner side for the arch of the foot, and the whole should be so wide as never to allow the flesh of the foot to be rubbed by overlapping its bevelled edge. All nails, wire stitches and wooden pegs should be carefully dealt with or removed. In light boots especially the waist should be sufficiently flexible to come up if necessary, and not force the foot down when the boot is laced. The vamp or whole front of the boot, if not soft, should be roomy enough to just hold the foot com-fortably when raised from the ground, and the toe or toe-cap should be high and wide enough to prevent the toes being cramped or the toe-nails pressed upon in any direction.

The Sole.—Given a sole of sufficient thickness and strength, we now come to one of the most important points in the whole of boot constructioni.e, the cut or shape of the sole. If we look at the foot, we see that the two large toes are as wide as the three smaller ones. If we take a base line running between the second and third toe to the centre of the heel, we shall find that it becomes a very simple matter to lay down definite rules as tothe shape that the sole of an ordinary boot should assume. If at the widest part of the foot we draw a cross line and make it of equal length on each side, this runs from the great toe joint to the little toe. If we divide the length of the foot into fifths we shall see that both the inside and the outside of the sole of the boot should be practically straight until the little toe is reached, or practically fourfifths of its total length. Years ago boots were too pointed, consequently the big toe was driven out-In order to obviate this, it was taught wards. that a boot should be straight on the inside from the heel to the point of the big toe, and in order to carry this view out, lasts were straightened on the inside without any due regard being paid to injury inflicted on the outer part of the foot (especially the little toes) by the outer side being curved too much and too soon, and made to resemble the convex border of a kidney or a boome-The last should have had something taken rang. away from it at the proper spot, and that something added to the outside at the proper spot. And so the boot could have been easily built on proper lines. Many of the old faults are being removed, and it is now possible to buy extremely comfortable readymade boots; but there is one fault still remaining which I have been unable to induce any shoemaker so far to give up. He seems unable to realise that the heel should not be set on in the line of the waist of the boot, but in relation to the base line of the foot itself. If the heels of our boots were turned, the right one a little outwards at the back and the left one correspondingly, we should then not tread the heels of our boots down in the way we do at present. I will illustrate these points by the diagrams I have brought with me. CORNS AND WARTS.

Now for a few words on the treatment of these troubles. As far as possible, of course, any known imperfections in boots likely to aggravate these conditions should be removed. Any corn can be rapidly cut down by a suitable file, and filing is a There is an far safer proceeding than cutting. cellent file in the market known as the Alexandra corn rubber, made apparently of dog-fish skin. It cuts a corn rapidly away, and if it becomes clogged it can be easily cleaned by a bit of cotton wood dipped in methylated spirit. Occasionally when a corn has been rubbed down the skin at the spot is still tender when the boot is worn. To meet this, more room can often be afforded, and therefore less pressure felt by wearing a thinner stocking for a time; or a corn plaster can be worn, or, better still very often, a strip of ordinary plaster above and below. Another simple expedient is to wet the boot just over the corn with very hot water, giving the water time to soak well in, and then wearing the boot all day so as to block the leather to the shape of the corn. The part of the boot so treated should be wetted with castor oil at night, as that will ensure that the leather does not set hard.

Plantar Warts.—It often requires a practised eye to recognise the presence of warts in the thick skin of the sole of the feet, because they usually form a part of a rather extensive callosity. Sometimes in such a callosity the warts are disseminated, and we only discover them by cutting away the hard substance until we expose little black dots or breeding points of still living papillary loops. Occasionally we find them complicating the painful condition known as Morton's disease. When they are disseminated, my practice is to cut them down until one can see their full extent, then to apply fuming nitric acid to every one of the spots which one can recognise as being warty. It is well to tell the patient that it may have to be done again, because you cannot be sure that the whole will be at once destroyed. After the nitric acid has had time to act, the excess is wiped off and a thin pad strapped on; patients can often go about during the treatment. Occasionally one or more of the points will become inflamed and suppurate. The patient should be told that this may happen, and that if it does he has only to come to you; the corn can easily be removed and the pain relieved, and then it requires only a short time and appropriate dressing to complete the cure. Sometimes the wart can be scooped out as a well-defined sodden little mass, either under gas or after a local anæsthetic has been administered. It cannot be too definitely stated that it is quite useless attempting to cure such plantar warts by the ordinary methods of chiropody for corns. If not treated they may last a lifetime and cause great suffering. If carelessly cut they may lead to serious, and even fatal, blood-poisoning. The simple corn can be simply treated, but the wart, and mixed condition of wart and corn, require skilful modern surgery.

THE SPIRILLUM OF VINCENT IN CERTAIN

## PATHOLOGICAL CONDITIONS OF THE MOUTH AND THROAT. (a)

By MILES B. ARNOLD, M.D., D.P.H.,

Assistant Medical Officer of Heal h to the County Borough of Blackburn.

I was led to the consideration of the organisms, described by Professor Vincent, when I was comparing films made direct from all the forms of throat infection that were at my disposal. I was surprised at the numbers of spirilla which could be seen on careful examination of films, and later on looking for them, I also saw fairly frequently fusiform bacilli.

The results of these examinations were as follows:—

In 15 cases of diphtheria, 4 showed spirilla or spirilla and fusiform bacilli.

In 20 cases of septic scarlatina, 7 showed spirilla, or spirilla with fusiform bacilli.

In 4 cases of post-scarlatinal (non-diphtheritic) infection, 2 showed spirilla, or spirilla and fusiform bacilli.

In 5 cases of follicular tonsillitis, 3 showed spirilla, or spirilla and fusiform bacilli.

In 3 cases of exudate from tonsillar crypts (non-inflammatory), 3 showed spirilla, or spirilla and fusiform bacilli.

In 5 cases of membrane forming after tonsillotomy, 2 showed spirilla, or spirilla and fusiform bacilli.

In 2 cases of wound in the gum 2 days after tooth extraction, 2 showed spirilla, or spirilla and fusiform bacilli.

The numbers of spirilla and fusiform bacilli varied from only a few in the film to enormous numbers, giving the typical appearance as described by Vincent. The last were three in number, and I will describe them in detail.

One was a case diagnosed as septic scarlatina with ulceration of the fauces. The spirilla and fusiform bacilli were present in numbers greatly in excess of any other organisms, but the case pursued the ordinary course of septic scarlatina, and films two days later no longer showed the typical Vincent's organisms.

The two other cases were children, æt. 7 and 8, convalescent from scarlatina. Yellowish patches appeared on the tonsils, in one case on both sides, and films showed only a few cocci amongst large numbers of spirilla and fusiform bacilli. These persisted four or five days and disappeared at the same time as the lesion. Neither of these cases showed any symptoms whatever. There was no rise of temperature, and no loss of appetite. Repeated cultures from the throat failed to show diphtheria bacilli, and there were no later complications. In addition to films from the throats, I was also making films from the detritus between healthy teeth. In no case where spirilla were found in the throat were they absent from the teeth. I also made films from the teeth of healthy children convalescent from infectious disease, and in 40 cases found spirilla in 29. From 10 healthy adults similar results were obtained in 6 cases.

As to the methods employed, I stained either with carbol gentian violet, or with carbol fuchsin. In about one quarter of the cases I examined hanging drop preparations for motility of the spirilla. This was very marked in some cases when taken from the throat, but was variable and may be mentioned as a character which seemed to distinguish the spirilla from the teeth from those from throat lesions. As to the identity of the organisms of the teeth with those of the throat, I have no evidence except that in all cases where they were present in the throat, they were also in the teeth. These organisms were present in considerable numbers in the cases of follicular tonsillitis, and when I examined exudate squeezed out from tonsillar crypts, which were not inflamed, they were present in each of the three cases. This occurrence of varying numbers of spirilla and fusiform bacilli in cases other than Vincent's angina is, of course, admitted by Vincent, who says that like other pathogenic microbes, they may occur as inhabitants of the mouths of healthy subjects.

<sup>(</sup>a) Paper read at the Buxton Meeting of the Royal Institute of Public Health, July, 1908, and printed in the Journal of the Institute in November, 1908.

I will now review the facts concerning the supposed effects of these organisms. Those interested in the questions of priority will find communications on the subject from Dr. H. Plaut, of Hamburg, and Professor Vincent in the Gazette des Hopitaux for February 14th, 1905. Professor Vincent gives a fairly complete account of his organisms and the angina of Vincent in the Lancet for May 13th, 1905. He distinguishes two forms of the angina. The first he calls the diphtheroid. The false membrane, adenitis and fever, make one think of diphtheria, but the bacteriological examination shows that it is not. In this variety the fusiform bacilli is found alone, or in association with streptococci, staphylococci, etc. He adds that it is important to remember there are cases in which the true diphtheria bacillus is associated with the symbiosis of the fusiform bacillus and spirillum.

The second form is the ulcerative membranous. In this the bacillus and spirillum are associated. There is malaise, headache and fever with injection of a tonsil. Soon examination of the throat shows a greyish or yellowish false membrane soft, not very thick and not very adherent, and beneath there is ulceration. The breath is fœtid and swallowing is difficult and painful. The submaxillary glands are enlarged. This angina lasts eight days or more, it sometimes affects both sides. Accompanying this form there may be a scarlatinal erythema and some times a pseudo-rheumatism. In the course of the disease albuminuria, myocarditis and endo-carditis may appear, but these complications result from an added infection, usually strepto-coccal. There is also described by Queyrat in the Gazette des Hopitaux, January 17th, 1905, a case which he says it was impossible, clinically, to distinguish from syphilis except by bacteriological examination, which showed it to be a case of Vincent's angina. Vincent himself, however, says that it is important to remember that secondary and tertiary syphilitic lesions may be infected secondarily by the fusiform bacillus and spirillum. But he considers that lesions which are true Vincent's angina may resemble syphilis, and only the result of treatment makes the diagnosis certain.

Lastly, I may add my own two cases in which bacteriological results were obtained typical of Vincent's angina, and in which there were no symptoms whatever, and the only signs were the small, yellow tonsillar patches. It seems to me, therefore, that before the possibility of this variable pathogenic influence is granted, there should be considerable evidence in its favour. There are certainly cases on record in which persons using the same tobacco pipe or having been in intimate contact have suffered, one after the other, from sore throats in which Vincent's organisms have been discovered, but as the organisms occur so frequently, such evidence must be on a large scale to be absolutely convincing.

An inoculation has been made on the wounded mucous membrane of the prepuce from the infected mouth of a patient and from the membrane growing on the site, Vincent's organisms were found in profusion in association with others; but there is no certain proof that the other organisms were not the more important factor. As to the effects of the inoculation in animals, Professor

Vincent himself, using impure preparations in which cocci were present, produced by subcutaneous injection abscesses, sloughing, and in some cases, wasting and death. Both cocci and fusiform bacilli were recovered from the lesions. Tunnicliffe, however, using pure cultures, did not get any pathogenic effects, and Lehmann and Neumann, quoting Mühlens, say that neither subcutaneous nor intraperitoneal injections into mice, rabbits, or guinea pigs showed pathogenic effects.

The question arises as to the relation of the fusiform bacillus in the spirillum. Professor Vincent regards it as most probably a case of symbiosis, but some consider that the spirillum arises from the bacillus, and Tunnicliffe in an apparently pure culture of the bacillus found the spirillum appearing. This result has been criticised, and I am not aware that it has been confirmed. It is, of course, possible that there is a large group of fusiform bacilli and spirilla which vary in their pathogenic characters as groups of other organisms are found to do so. Apart from this theory it seems to me that the evidence in favour of the pathogenicity of Vincent's organisms is not strong enough to enable one to consider it proved. That they can flourish as parasites is certain, but they are found in cases of widely different clinical appearances and in a class of case notoriously difficult to diagnose, and also, they are often found in association with organisms known to be capable of producing the pathological conditions seen. They are also found in numbers varying from only a few in a film to such numbers as to practically fill the field. Professor Vincent, himself, acknowledges their presence in the mouths of healthy subjects and that they grow profusely in lesions which they have not caused. The only inoculation experiments with pure cultures that I am aware of were negative. On the other hand, taking a tonsillotomy wound in a healthy subject as a simple wound in the mouth, I have not obtained a typical film from the exudate which forms during the days following the operation, though in two cases, fusiform bacilli and spirilla were present in small numbers. Only five opportunities, however, have occurred of trying this.

In conclusion, I must thank Dr. Knyvett Gordon, and Dr. Alfred Greenwood for allowing me to use cases in the hospitals of which they are superintendents.

#### ON THE USE OF

### DIGITALIS IN DISORDERS OF THE PERIPHERAL CIRCULATION.

By J. T. MACLACHLAN, M.D., Assistant Physician, Glasgow Royal Infirmary.

During the present winter I have been impressed with the number of patients who suffer from cold feet and hands. In cold weather their hands are almost livid red, and the face deeply congested with a bluish tinge. Such patients are apt to suffer from chilblains, going on occasionally to trouble-some ulceration. Bunions and corns, too, appear to me to be especially common in such patients. The pulse is soft and easily obliterated. It appears to me the condition is not one of weak heart so much as lack of tone in the arteries. In those cases digitalis acts like a charm, and it is astonishing to find, after a week's treatment by digitalis, the condition is promptly relieved. But it is essential to

prescribe a reliable preparation of digitalis, and I have found Parke, Davis and Co.'s digitalis give

A somewhat similar condition is present in young women suffering from gastric ulcer, and I cannot help thinking that the defective peripheral circulation has an ætiological bearing. I feel tolerably certain that the addition of digitalis to the other remedies is of essential importance.

Again, in patients the subject of phthisis pulmoralis the pulse seems to me to partake of the characters described above; but, once again, digitalis is useful. It is a significant fact that tubercle is apt to deposit at the apices, and, as far as I can judge from clinical observation, at the points where the lungs divide into their lobes.

The tendency to enlargement of the terminal phalanges, or, indeed, of the whole hand, may be

related to a tardy peripheral circulation.

Apart from these disabilities, patients with the state of the circulation I am attempting to describe enjoy a happy optimistic state of mind, while those with very tense arteries are frequently depressed, moody and irritable.

Ulcers on the legs or hands, persisting in consequence of a poor peripheral circulation, often take a "turn for the better" when the circulation is improved by the administration of digitalis.

Vertigo is very common in persons the subject of heart disease, and anyone complaining of it should receive a careful examination, for valvular disease will be frequently discovered, and will furnish the key to the successful treatment. The circulation of blood through the brain is evidently disturbed, and once again cardiac tonics are neces-

We are apt to look upon the circulation of the blood as being entirely an affair of the heart, whereas I believe the muscular coat in the arteries is no less necessary in maintaining it in an efficient state.

#### **OUT-PATIENT'S ROOM.**

ST. THOMAS'S HOSPITAL.

Demonstration upon a Case of Abdominal Pain.

By EDRED M. CORNER, M.C., F.R.C.S.

This is the case of a woman, æt. 25, who has had an appendix abscess opened and drained two years ago. The scar is just above and parallel with l'oupart's ligament. Lately she has developed attacks of abdominal pain, due to peristalsis of the bowels, coils of which can be felt to rise and harden under the hand during The abdomen becomes distended with gas, her attacks. and when flatus is passed the attack is relieved. There is no sickness, only eructations. The attacks last from 10 minutes to an hour, and are accompanied by a weak, rapid pulse, with blueness of the extremities. abdominal examination of the patient reveals little of importance except a little resistance on the inner side of the operation scar. Per rectum, no tumour can be felt; the uterus and adnexa are healthy. In the absence of definite physical signs, it is necessary to rely upon the patient's history and our own experience to give advice. Since Christmas, 1908, I have had no less than three somewhat similar cases, and as they illustrate the reasons upon which my advice to the patient is based, I will briefly recall them.

The first was a man of 40 years of age, admitted to the hospital for acute intestinal obstruction of eight days' duration. The man was, naturally, exceedingly ill, and it was doubtful if it was worth his while to be operated upon. It was decided to give him the chance. The abdomen was opened through the right rectus muscle, and the cæcum found to be collapsed. The appendix was adherent to the mesentery of the ileum, and from this point a band encircled and obstructed the small bowel. There is no doubt that this band resulted from previous appendicitis. The poor man died 12 hours later, never recovering from the operation. The post-mortem examination confirmed

the observations made at the operation.

The second case was one of Dr. Underhill's patients at Herne Hill. I had removed the appendix for recurrent attacks of appendicitis a year before. He had now intestinal obstruction of a week's duration At the operation no time was lost in finding the obstruction, as the first case had taught me. There was a band extending from the mesentery across the small bowel, obstructing it, about a foot from the cæcum. It was divided, but the man never rallied from the operation, dying a few hours later.

The third case was one from whom the appendix had been removed two years before by another surgeon. It was that of a young man with nine to ten days' history of intestinal obstruction. At the operation an obstructing band was found across the ileum, about 16 in. from the cæcum, precisely as in the other cases. It was relieved, but the man never rallied, dying six hours later.

These cases agree completely on the following clinical points, and, in doing so, accentuate their importance:—
(1) The causation of the intestinal obstruction was appendicitis; in two cases the appendix had been removed; in one it had not. (2) The band causing the obstruction was over the small bowel, a few inches from the cæcum. (3) The consequent obstruction was incomplete, the symptoms slight, so that the cases went over a week before coming to operation. (4) All died, rever rallying from the operation, in consequence of the long illness entailed. (5) The obstructing band had arisen from an adhesion between the small bowel and its mesentery, in consequence of an attack of appendicitis. The adhesion became drawn out into a band by the peristalsis of the intestine.

It is a very old teaching that cases that do badly instruct us much more than do cases that do well. This is a doctrine which is very true in the present instance, because the three fatal cases just narrated form the basis for advising this woman to have an exploratory operation. If my diagnosis is true, the three men who have died have helped this woman. The diagnosis made is that of partial intestinal obstruction from adhesion of the ileum near the cæcum, the consequence of the previous attacks of appendicitis. I may add that the patient has been examined by physicians, who regard her trouble as "functional," and her dislike to the ward discipline suggests that also. But there is reason to doubt if her whole trouble is functional. It may very well be a mixture of sub-acute intestinal and neurasthenia which may have resulted from it. treatment of the case has been decided. She is to be treated with regular diet, mental and bodily rest, regulation of the bowels, and general discipline. If definite attacks of partial intestinal obstruction occur, the abdomen will be explored and the band divided; or if, instead of a band, multiple adhesions are found which, if separated, will re-form, it will be better to make a lateral anastomosis between her ileum and het transverse colon.

#### OPERATING THEATRES.

ITALIAN HOSPITAL, QUEEN SQUARE, W.C. OPERATION FOR ACUTE APPENDIX ABSCESS, BY T. P. LEGG.—A man, set. 30, was admitted, complaining of pain in the right side of his abdomen, and having also a temperature of 1010. He had been quite well up to a few days before coming to the hospital. The pain came on very suddenly and severely. He was not sick, and, on examination, was found to have rigidity in the right iliac fossa and extreme tenderness on palpation; no tumour was detected. The rest of the abdomen was a little distended, but otherwise normal; the pulse was 100, tongue clean. During the course of the next two days the temperature and the pulse came down to normal, and he appeared to be much better. On the sixth day of his stay in hospital the temperature rose suddenly to ioi.9° in the evening; next morning it was 102.4°, and he was much worse. The pain and rigidity had returned, the abdomen was distended, and

a definite swelling was found in the right side of the abdomen. This swelling was behind the rectus muscle; its lower limit was a little below the level of the anterior superior iliac spine. It measured about 3 in. transversely, and 4 in. from above downwards, and was resonant on percussion. There was no swelling in the right iliac fossa, and no resistance in this situation. Operation was undertaken at once, an incision 3 in long being made over the centre of the swelling. On opening the peritoneal cavity, no adhesions were found. opening the peritoheat cavity, no additional states of the distended and inflamed ascending colon presented, and on its inner side an elastic swelling was felt, covered by small bowel. The colon and the small intestine were pushed off the swelling by means of the general states of the general states. gauze packing, which also served to shut off the general peritoneal cavity. A short incision was then made into abscess, and several ounces of fæculent pus were slowly evacuated, the pus being mopped up as it escaped. After all the pus had been evacuated, the incision into the abscess cavity was enlarged, and the finger inserted to see if the appendix could be felt or if there was any concretion lying loose. Neither the appendix nor a concretion was detected. A large drainage tube was placed in the cavity and packed round with gauze. An outside dressing having been applied, the

patient was sent back to bed. Mr. Legg said that this case was an excellent example of an abscess due to appendicitis, occupying a high position behind the colon. It was not a very uncommon position, and the case illustrated the usual signs of such abscesses. In these patients there were frequently no adhesions shutting off the general peritoneal cavity, and hence, in operating on them, one had to very carefully pack off with gauze the peritoneal cavity before opening the abscess. Moreover, in opening the abdomen, the presence of distended and inflamed intestine in front of the abscess must not be forgotten,

and, if care is not taken, the bowel may be wounded either on dividing the parietal peritoneum or in opening the abscess if it is not carefully and sufficiently displaced. It was always best to make a small incision into the abscess; the pus can then be easily mopped up, and the whole wound is not flooded by it. By doing it in this way, Mr. Legg thought that the chances of infecting the general peritoneal cavity were much diminished. After the evacuation of the pus, the incision should be enlarged sufficiently to permit of a finger being inserted to feel for any loose concretion. Mr. Legg did not approve of making a search for the appendix by breaking down the adhesions and the abscess wall. He thought it was much more preferable

to leave the appendix alone, and, when the wound had healed, to remove it by a second operation. This was usually necessary, experience having shown that in these cases the appendix was so destroyed that the whole or greater part of it would be found to be chronically inflamed and capable of determining the formation of another abscess. Of course, if the appendix could be seen and felt when the abscess was opened, it was right to remove it, but this was not the same thing as searching for it by breaking down the abscess wall. Mr. Legg also did not think any advan-tage was to be gained by washing out these foul abscesses. He trusted to the drainage by means of a

large tube, and in the course of a few days the pus soon became odourless. The gauze packing would be removed on the fourth or fifth day, and replaced by a smaller quantity packed around the drainage tube, which would be gradually shortened.

The case clinically was interesting, because the patient after his admission seemed to make a rapid recovery; the temperature and pulse came down to normal, and the abdominal signs cleared up. Then suddenly he became very ill, the temperature and pulse rapidly rose, and the signs of an abscess were evident. This type of case was not uncommon, and the danger arose from their deceptiveness. One must suppose the abscess had been deeply placed and slowly forming all the time, and that suddenly it rapidly increased. Had the patient not been kept in bed the whole time, and carefully watched, the results might have been fatal. A patient who has had an attack of appendicitis, with high temperature, should always be kept in bed and closely watched for days after the symptoms have sub-

sided, and when a rapid recrudescence of the symptoms occurs, the presence of an abscess should be carefully looked for, and the necessity of an immediate operation borne in mind. Repeated examinations of the blood for a leucocytosis should be made, and in this patient there were nearly 20,000 on the day of operation.

It is satisfactory to record that the man made an

uninterrupted recovery.

#### TRANSACTIONS OF SOCIETIES.

CHELSEA CLINICAL SOCIETY.

MEETING HELD FEBRUARY 16TH, 1909.

The President, Mr. A. F. PENNY, F.R.C.S.I., in the

A PAPER was read by Dr. ALFRED EDDOWES on BOOTS, AND THE TREATMENT OF CORNS AND PLANTAR WARTS,

which will be found elsewhere in the present issue

(page 215).

Dr. FIRTH PALMER maintained that the prevention and cure of corns was perfectly simple, and that nine-tenths of the suffering in the world resulting from corns was due to the existence of chiropodists. The painful warts referred to by Dr. Eddowes he thought

largely the result of cutting corns.
Dr. Marsh was sceptical as to the possible value of

the Alexandra corn rubber.

Dr. SIMMONS took exception to all the boots recommended by Dr. Eddowes. He had never been able to obtain a suitable boot in this country, and always ordered American ones

Dr. Eddowes replied.
Dr. Victor Bonney read a paper on SOME USEFUL PRESCRIPTIONS IN THE PRACTICE OF GYN.ECOLOGY.

Gynæcology was almost a purely surgical art, but there were a certain section of patients who refused the administration of drugs either as an adjuvant or as an alternative to operative measures. It was possible as an atternative to operative measures. It was possible to divide the women attending an out-patient clinic into (1) those who had physical signs of disease, and (2) those who had none. It was the last group in which drug treatment was chiefly indicated. Of the drugs in the gynacological materia medica, ergot was by far the most useful. It was the only one possessing a completely specific action. He had found it most active in acid solution, and combined with strychnine. There were certain contra-indications to its use, of which the most important were—(1) it should not be used as a treatment for uterine fibroids. These tumours should be removed by operation as early as practicable. The continued use of ergot by increasing arterial tension threw an increased strain on the cardiac muscle, already degenerate from chronic anæmia. The dilatation that ensued militated against the success of the almost always inevitable operation. (2) It should not be used as a treatment for incomplete abortion. The proper treatment was uterine exploration. To waste time giving ergot increased the risk of sepsis. (3) It was a useless drug in diffuse fibrotic metritis. In these cases, as a result of chronic inflammetrius. In these cases, as a result of chrome inflammation, the uterine musculature was degenerate, and ergot produced no effect in controlling the severe menorrhagia from which such patients suffered. (4) Finally, it should never be given to check uterine hæmorrhage without having first made a digital examination as to the cause of the bleeding. Neglect of ination as to the cause of the bleeding. this point was responsible for a large number of the inoperable cases of carcinoma of the cervix which came before a surgeon. There were several drugs having actions more or less akin to ergot. Of these the speaker had favourable opinions of the salts of cotarnin called styptol and stypticine. Hydrastis and cotarnin caused styptol and stypticine. Hydrastis and hammamelis were useful adjuvants, whilst he had had very good results with bryonia, especially in cases of menorrhagia associated with chronic pelvic pain. Cotarnin also had this pain-allaying property in a degree. Of the so-called "uterine tonics," the bromides

were the most useful. It was a curious thing that in women suffering from debility and pelvic pain the bromides acted as very efficient tonics, whilst strychnine was always disappointing in these cases. He had had very good results with aletris, especially when combined with bryony and the bromides. For dysmenorrhea various analgesic drugs were at the service of the gynæcologist. He preferred phenalgin amongst these. This failing, he fell back on some others in the list. The analgesics were of great use in virginal dysmenorrhæa, but much less so in the various acquired forms of the affection, while in the treatment of chronic pelvic pain they had no place at all. In these cases the bromides, aletris, viburnum, or cotarnin were indicated. Passing to the use of local applications, the speaker spoke highly of protargol in vaginitis. It was important in such cases to make direct application to the cervical canal as well. He discussed briefly the various forms of douche. For deodorant purposes the best form, in his opinion, was a Sanitas douche. Speaking of pruritus and its treatment, he mentioned the proprietary compound "zymocide," which had yielded admirable results in compound this affection.

### NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD AT LIVERPOOL ON FEBRUARY 19TH.

The President, Dr. J. W. MARTIN (Sheffield), in the Chair.

Dr. J. J. O'HAGAN showed a fibro-myomatous uterus, with bilateral ovarian dermoid cysts, which

had been removed by total hysterectomy.

Dr. J. E. GEMMELL and Dr. LEITH MURRAY (Liverpool) showed: (1) Myxo-fibroma of the vagina; (2) sarcoma of the great omentum, which had presented a soft solid, freely movable tumour in the left hypochondrium. It could be pushed into the pelvis, and had simulated a dislocated spleen. It was easily excised. There was no ascites, and the other excised abdominal organs were normal.

Dr. D. LLOYD ROBERTS (Manchester) showed a specimen of cystic fibro-myoma of the uterus, and read the notes of a case of Cæsarean section, performed, before the onset of labour, on account of a flattened pelvis (C.V. = 3 ins.). Craniotomy had been performed on three previous occasions. Involution of the uterus was slow, and on the eighth day symptoms of sepsis appeared. The uterus was explored and a large clot removed. Recovery was then uninterrupted.

In closing a discussion, Dr. LLOYD ROBERTS stated that he always, if necessary, dilated the cervical canal before suturing the uterine incision, that ergot was given during the operation, and that, in his opinion, the retention of blood-clot was due to pressure of the lower uterine symphysis against the promontory.

Dr. LLOYD ROBERTS also showed a recurrent tumour of the vagina, enucleated, piecemeal, from a woman, et. 43. Microscopically it consisted chiefly of fibromyomatous tissue, though one part suggested sarcoma.

Dr. J. E. Gemmell stated that, nine years before,

he had enucleated a vaginal growth, the size of a Jaffa orange, from this patient. Clinically he had considered it a sarcoma, but microscopically it had been described as a degenerating fibroid.

Dr. J. W. FITZGERALD (Manchester) showed the

specimen and read notes of a case of primary carcinoma of the vagina, occurring in a nullipara, æt. 26. The ulcerated growth, which occupied the left fornix, was freed from below and then removed, together with the uterus by the abdominal route. The patient made a good recovery. Section showed that the growth—an epithelioma—though invading the cervix, was not connected with the mucous membrane of the cervical canal. But it may possibly have arisen from the epithelial covering of the portio.

Dr. H. R. CLARKE (Manchester), in a paper on cavernous conditions occurring in the uterus, pointed out that the myometrium of the infantile uterus consists of a network of a fibro-muscular tissue, enclosing

large cavernous spaces, which are lined with endothelium and filled, in most of his specimens, with blood. During development arteries extend from the fibrous trabeculæ into these spaces, invaginating the venous wall and producing, in the early stages, a condition which the author likened to corpus cavernosum of the penis. The arteries grow more rapidly than the venous spaces, and so, by this process of condensation, the dense condition of the adult myometrium is reached, and the arteries of the adult uterus come to be surrounded by their venous spaces. The author suggested that the angiomatous changes seen occasionally in uterine fibroids may possibly be dependent upon this developmental process.

The paper was discussed by Dr. Blair Bell, Dr. Lloyd Roberts, and Dr. A. W. W. Lea, and Dr. Clarke replied.

#### ULSTER MEDICAL SOCIETY.

MEETING HELD THURSDAY, FEBRUARY 18TH, 1909.

In the absence of the President, Mr. T. S. Kirk, the chair was taken by Professor Sinclair.

Dr. MAGUIRE showed a case of acromegaly. The patient was a woman of about 45, with a history of the disease having started 15 years ago. The appearance of the hands and feet was quite typical. She had recently been operated upon for sarcoma of the lower jaw, and Dr. Maguire said that the idea naturally occurred to one that this might have been secondary to a tumour of the pituitary body. But he could find no evidence of such a tumour, and Dr. Cecil Shaw, who had kindly examined the eyes, found no defect of sight. The larvnx could not be seen, owing to the large size of the tongue and the patient's inability to open the mouth widely. A curious feature was the functional activity of the mammary gland, from which milk could easily be squeezed, though it was four years since a child had been nursed. Dr. Maguire showed excellent skiagrams of the hands and feet, which his

colleague, Mr. O'Doherty, had done for him.
Captain Archer, R.A.M.C., showed two cases. The
first was a soldier suffering from what seemed to be irritable heart. The heart ran at about 160, the impulse almost imperceptible generally, with every sixteenth beat or thereabouts very strong. The only point in his history throwing light on it was that just before coming into hospital he had overstrained himself in a long march. The second case was one of persistent pain after a fracture of the clavicle, due apparently to involvement of the brachial plexus.

Dr. Calwell opened a discussion on GASTRIC ULCER.

After considering its distribution, and the age and sex of patients, he made several divisions of the ailment, according to the nervous symptoms, migraine, etc., accompanying it, or the symptoms of infection of the alimentary canal. He emphasised the importance of early treatment, and specially of rest. Referring to chronic ulcer, he asked the opinion of his surgical colleagues as to the indications for operation. His own opinion was that where the surgeon could relieve a mechanical difficulty he did good, but not otherwise.

Professor Lindsay discussed the foregoing remarks,

and laid special emphasis on the differential diagnosis of ulcer from gastralgia.

Dr. DEMPSEY said he was not convinced of the advisability of making the various classes of ulcer which Dr. Calwell had named. After his remarks it was agreed to adjourn the discussion till the next

#### CENTRAL MIDWIVES BOARD.

MEETING HELD THURSDAY, FEBRUARY 25TH, 1909.

Dr. CHAMPNEYS in the Chair.

THERE were also present Dr. Stanley Atkinson, Mrs. Latter, the Hon. Mrs. Chas. Egerton (who has been appointed by the Privy Council in the place of Miss Wilson, resigned, Miss Paget, and Mr. Parker Young. Letters were read from the Registrar of the Royal

College of Surgeons reporting that Dr. F. H. Champneys had been reappointed to represent the College on the Board, and from the Clerk of the Society of Apothecaries of London stating that Mr. Parker Young had been reappointed to represent that body. Frederick Edge, M.D., F.R.C.S., Wm. Gough, M.B., F.R.C.S., and (pro hdc vice) George Raymond, M.B., were approved as teachers; and Dr. J. D. Barris, of the City of London Lying-in Hospital, was appointed as one of the Board's supernumerary examiners.

A letter was read from the Clerk of the Council, stating that, in the Lord President's opinion, the practical objects of the Midwives Act Committee would not be served by the addition to its numbers of repre-

sentatives of special interests.

Mr. PARKER YOUNG moved a resolution of regret at this decision, which was seconded by Dr. ATKINSON, who remarked that the Privy Council had just appointed a representative of special interests in the person of a County Medical Officer. The resolution was passed, nem. con.

suggestion from Mrs. Hobhouse "that all Registrars of Births should add in a new column the name, status, and address of the person who delivered the child," met with the approval of the Board, and it was agreed that the Registrar-General should be asked to issue the

necessary instructions.

In view of the correspondence which has arisen on the subject of vaginal examinations consequent upon instructions recently issued by the Board to training schools and teachers, the following circular has been issued, signed by the Chairman:—

VAGINAL EXAMINATIONS—RULE C. I. (1).

Inasmuch as misapprehension seems to exist with regard to the meaning of Rule C. I. (1): "She must have . . . attended and watched the progress of not fewer than 20 labours, making abdominal and vaginal examinations during the course of labour" (see also schedule, Form III.):-

The Board wishes to point out that the word "exam, inations" (in the plural number) is to be taken in connection with the word "progress," and as implying such a number of examinations as will enable the pupil to "watch the progress of the labour." The word "frequent" is advisedly not used.

#### CORRESPONDENCE.

#### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Feb. 28th, 1909.

FULGURATION.

The treatment of cancer by fulguration seems to have been definitely adopted by French surgeons.

The term "fulguration," invented and applied by Dr. Keating-Hart, is an electro-surgical operation which, as its name implies, is divided into two periods —the operation proper and the application of the electric spark of high frequency.

These manœuvres being very painful, local or general

anæsthesia is necessary.

The patient being placed under the influence of an anæsthetic, a preparatory application of the electric spark is made so as to soften the tissues of the neo-plasm to render them more amenable to the curette and anæmify the surface.

Immediately after this fulguration, the tumour is excised with the bistoury and the raw surface carefully scraped with the curette. Fulguration is then practised, which has for almost immediate effect the arrest of

Keating-Hart uses a special electrode of his own invention to operate. This electrode is either straight on curved, so as to be able to act in every region. The spark does not act solely by the heat it develops in burning the morbid tissue; the cells of the neoplasm melt, so to speak, under its influence, while it stimu-lates the vitality of the neighbouring healthy tissues.

The duration and dosage of the sparks are difficult

to fix precisely, as a great deal depends on the operator, his experience in fulguration, and the immediate effects on the tissues. In any case, no portion of the wound should be neglected, and the edges particularly should receive special care.

Almost at the beginning of the fulguration the hæmorrhage is rapidly arrested; the surface becomes white, but soon afterwards it takes on a blackish-grey aspect. The operation terminated, the

dressed.

Dr. Keating-Hart insists on two very important points: First, each time that it is not possible to completely remove all the cancerous masses the region must be submitted to continued refrigeration by means of the ice bag or an uninterrupted current of iced water; secondly, oxygen water only must be used, more or less diluted, for washings and dressings.

In cases where dry dressing is sufficient, he powders the wound with perborate of soda. A few days after the operation. ordinary antiseptics, such as iodoform

and aristol, may be used.

As to the consecutive phenomena, the first to be noticed are complete and absolute suppression of pain, and an extremely abundant secretion of the wound. requiring the dressing to be changed several times a day, followed a few days subsequently by active granulation. The wound is completely cicatrised in from eight to ten weeks.

Dr. Bizard, who has made a special study of this treatment, says that, although fulguration cannot be applied indistinctly for every visceral or cutaneous cancer, yet it cannot be denied that it constitutes an excellent method for a whole group of neoplasms which were hitherto regarded as entirely inoperable. It is the only method which allows hope to be entertained for the most desperate cases, such as cancers of the face invading the cavities and gaining the osseous canals and inaccessible infractuosities which have resisted every treatment, medical or surgical.

One great advantage of this new treatment of malignant disease is that it is absolutely inoffensive, since Keating-Hart used it in over 200 grave operations

without one accident.

#### IMPETIGO AND NEPHRITIS.

Impetigo in children is frequently accompanied with nephritis, the result of the cutaneous lesion; the impetigo disappears first, and afterwards the symptoms of the renal complication.

Two clinical types are observed—the transitory and the acute form.

The first type is found in cases where only slight symptoms are noticed, and which are only confirmed by examination of the urine. The presence of albumin is the only symptom. The quantity varies between 10 and 15 grains to the quart, but it can become more abundant. Hæmaturia has been observed histologically by microscopic examination, but sometimes the amount is sufficient to colour the urine. The sediments observed under the microscope, besides the red corpuscles already mentioned, are epithelial cylinders and hyalins. The other symptoms usual to nephritis are absent; neither œdema, cardiac trouble, nor uræmic symptoms are observed. Definite recovery is the rule.

Otherwise serious, says Dr, Girard, is the nephritis beginning either by the skin or the lower limbs, and

sometimes general anasarca has been observed.

Besides these cases, there are others where the cedema. is hardly perceptible; a puffiness of the face and a waxy colour of the skin would represent all the abnormal signs The heart is in no way disturbed, and nothing is found in the lungs, but examination of the urine reveals the presence of a more or less large quantity of albumin.

In grave cases of renal complications, with impetigo, the child is pale and very thin, the eyelids somewhat puffy, the abdomen large, with voluminous liver, the heart dilated, and the pulse rapid and irregular; urine high in colour, dirty, and contains about a drachm of albumin to the quart.

A serious complication is possible in the course of this nephritis. Cardiac symptoms may supervene, producing uramic symptoms which put the life of the patient in grave danger, anasarca, oliguria, dyspnœa,

epistaxis, vomiting, etc., as were observed in cases cited by Muller and Marfau.

In the course of impetigo, nephritis is consequently a complication that should not be overlooked; the urine of every child suffering from impetigo or impetigenous eczema should be examined, and an appropriate treatment in the case of the existence of albumin prescribed.

On the rapidity of the diagnosis, and consequently on the efficacy of the treatment will depend the nature of the prognosis. Benign in the majority of cases, it can become very grave, this being due, perhaps, to a special virulence of the infectious germs at the seat of the cutaneous lesion, or to the general weakness of the patient.

In any case many of the complications can be

avoided.

GONORRHOBA. Salol, Urotropin, gr.

Santalol, 4 gr. For 1 capsule, 6 to 12 daily.

The simultaneous administration of urotropin, salol, and santalol seems to have an excellent effect on acute or chronic blennorrhagia. It can be commenced at the very outset, and prolonged without inconvenience to the general health.

#### GERMANY.

Berlin, Feb 28th, 1909

At the Medical Society, Hr. Unger showed a dog in which, ten days previously, he had removed both kidneys, as well as the ureters, and a portion of the aorta and vena cava, implanting in their places the corresponding parts of another dog. The animal was apparently doing very well.

The discussion on Hr. Albu's paper on VISCERAL PTOSIS AS A CONSTITUTIONAL DISEASE

was then continued.

Hr. Kausch remarked that the thorax phthisicus and the thorax paralyticus were not identical. The former had certain distinguishing marks at the upper aperture which were wanting in the latter.

Hr. Bönniger considered splanchnic ptosis to be a result of space conditions; it was therefore dependent on the form of the lower thoracic aperture. Normally in the infant the organs lay very low; it was only when the liver, which was at first very large, became reduced to the proportions of later life, and space was obtained there, that they rose higher. The most favourable means of avoiding splanchnic ptosis lay in raising the capacity of the lungs by corporeal development of the child, and thereby influencing the form of the

thorax in a favourable manner.

Hr. L. Landau considered splanchnic ptosis, with few exceptions, not to be a congenital disease, but one caused in later life by mechanical or anatomical changes; movable kidney, or liver, spleen, or other organ was not a secondary, but an independent affection. It occurred through the giving way of the means of fixation. As regarded the liver, the ligamentation exceptions of the secondary of mentum ersonarium, or teres, or rotundum played as insignificant a part as the round ligaments of the uterus; they could at most prevent extreme displacements. For the purposes of fixation, the space in the abdomen, the amount of fat, and the abdominal walls were more to be considered. This view was important also as regarded treatment. From this point of view it was of no use to fix up one prolapsed organ; it was much more important to strengthen the abdominal muscles by exercises. During the intervals of treatment and whilst at work a corset or bandage might be

Hr. M. Mosse thought that anatomical examinations were wanting for the statements made by Albu, as percussion did not always give the limits of the stomach and intestines, especially in infants. Ptosis of the abdominal organs might be either congenital or acquired. The latter was not generally an object for treatment, as it did not, as a rule, cause any symptoms. Prophylaxis was the best treatment, a proper supervision of the corporeal development.

Hr. Posner had repeatedly observed renal palpatory albuminuria. This might be of importance; even

renal hemorrhage might take place from energetic pal-pation of a movable kidney. One should be careful, therefore, not to do harm by abdominal massage, or allow bandages to be worn that caused a constant pressure on the kidneys. Hr. Fuchs drew attention to the muscular weakness present in various parts of the body in patients who suffered from splanchnic

After Hr. Albu's reply, Hr. Hartog followed with a NOTE ON EARLY GETTING-UP AFTER LAPAROTOMY. In his remarks he endeavoured to combat the objec-

tions that were in force in regard to allowing patients to get up quickly after laparotomies. Hæmorrhages and giving way of the wound should be guarded against by careful technique, the wound being covered by a plaster dressing and a supporting bandage. Small emboli were possible, but only during the early days when the thrombus was fresh, and soft, and harmless. In his own experience thromboses were less frequent with early getting-up. Besides this, there was the advantage of earlier convalescence, and earlier spontaneous action of the bowels, when, if the patient was to be allowed to get up early after operation, it was a necessary condition that the wound should have healed by first intention, and that there should have been no fever. The will of the patient, too, counted for a great deal. The speaker did not think it right to permit a patient to get up before the third day, and she should not be allowed to leave the klinik before the fourteenth day.

## AUSTRIA. Vioana, Feb. 28th, 1909.

ATRESIA RECTI.

Moszkowicz showed an infant one month old to the Gesellschaft on whom he had operated for atresia of the rectum. He first made an opening into the left iliac fossa, where the flexura sigmoidea was opened, from which a large quantity of meconium was discharged without any subsequent peritonitis. After the child had recovered, and the bowel fairly emptied, an attempt was made to complete the opening at the rectum on the seventeenth day, where a normal exit of the fæces could be accomplished. Before commencing the operation, the cul-de-sac was washed out, and a fluid solution of metallic bismuth poured in through the fistula, and the whole afterwards examined by the Röntgen rays. It was then seen that the cul-de-sac passed down close to the perinæum, into which a pair of forceps were placed, and the part distended so that a circular opening could be made from the outside to form an anus. The mucous membrane of the bowel was then brought down and attached to the outer skin. The child has since been able to pass its stools by the natural channel, while the fistula closed without any other interference, but has now a tendency to narrow the lumen of the bowel.

NEURO-FIBROMATOSIS.

Zumbush next presented a man, æt. 22, with a large, dark, hairy, pigmented mark on the left cheek and temple. These thick, dark, bristly patches were strewn over the trunk and arms, ranging from the size of poppy seeds to the palm of a hand. They were sharply defined, and the texture of the skin in the neighbourhood was unchanged. In these patches were concentric rings rising in tiers, having a livid colour, and hard, but some of them were soft and could be pressed level with the healthy skin when the finger was drawn across the two surfaces and then became quite indistinguishable to the observer. The right tibia from the middle outwards had a sabre appearance, while posteriorly it was crooked and irregular, with a pes planus valgus of the foot. The fibula under the Röntgen ray appeared as a thin withe, but not bent or irregular like the tibia. He considered all these changes as congenital morbid productions.

#### ERYTHEMA INFECTIOSUM.

Escherich presented two children with what is known as erythema infectiosum, which, he considered, would be more correctly described as erythema multiforme. These children had a rash resembling scarlet fever and measles combined. It is epidemic, and attacks children from 4 years to 12. The youngest patient he has ever seen suffering from the disease was 14 months. The

rash appears on the face without any constitutional prodroma in the form of bluish red, slightly elevated patches of erythema, extending from the alæ of the nose to the ears, but preserving the forehead in a great measure. The lymphatics below the ears are usually tender and painful to the touch. Along the extensor side of the limbs, as well as the gluteal region, the measle rash in large patches is met with, but it is less pronounced, and not so well defined over the trunk. It usually lasts from 8 to 14 days, with varying intensity, having a reticulated marble appearance before disappearing. Lymphatic enlargement, except those below the ears, mucous catarrh, and general disturbance, are all absent; neither are there sequelæ or other complications arising to retard recovery. It is evident that scarlet fever, measles, or rötheln may be easily confounded with the disease from its frequent recurrence and general appearance during an epidemic of measles. Some authors, like Hebra, draw distinctions between this infectious disease and erythema multiforme, although both agree in the localisation and efforescence of the rash, but differ in respect to contagion, affirming that erythema multiforme is not infectious, while exthema infections in Factorial and the statement of tious, while erythema infectiosum is. Escherich expressed some doubt about the contagious nature of the disease, as he has frequently met with it in different departments of the hospital, where it should, in all probability, have spread, but was easily confined to sporadic individuals. He thought we might easily retrace our steps and place both of these morbid changes under crythema multiforme.

Ehrmann concurred with Escherich that this was only an abortive form of erythema multiforme exsuda-

tivum, and not an acute exanthemata.

### FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

THE CARNEGIE TRUST.—The Report of the Trust for the year 1907-1908 has been awaited with peculiar interest, because the end of the academic year with which it deals marks the close of the first quinquennial period of its operations, and, with the coming year, a new scheme of grants comes into force. A new denew scheme of grants comes into force. A new departure was made by the Trustees in admitting the Press to their deliberations, and the wide publicity which has thus been given to the speeches of the chairman, Lord Elgin, and Mr. A. J. Balfour, renders it unnecessary here to do more than refer to some of the salient features of the Report and meeting. It is especially interesting to observe how, in the opinion of all concerned, the endowment of research ranks in importance above the provision of better equipment, and far above the payment of class fees. In regard to the last-named department of their work, the Trustees have been guided by two principles: first, an adequate and uniform test of preliminary education; and, second, conditions of University study such as shall best serve the educational interests of the beneficiaries. These principles are now on the point of becoming fully operative. It will be remembered that in the trust deed Mr. Carnegie expressed the hope-or perhaps rather merely the opinion—that some part of the class fees would ultimately be refunded by the beneficiaries. This has been done by 55 out of a total of 8,263 students, the voluntary repayments amounting to £880 of a sum of £298,686 expended. The Trustees have been furnished with reports on the work of Carnegie scholars by Dr. Dobbie, Director of the Royal Scottish Museum

—Physics and Chemistry; Dr. Ritchie, Superintendent
of the Laboratory of the Royal College of Physicians, Edinburgh-Biology and Medicine; and Professor flume Brown—Historical and Economic. It is satisfactory to read that in nearly all cases the standard of work has been high. Dr. Ritchie expresses the opinion that in no corresponding period in the history of the Scotch Universities has so much research work on uniformly high standard been successfully carried on. He adds that the Trust is responsible for this development, and that without its assistance the work would in many cases never have been undertaken. Dr. Hume Brown refers to Mr. Duncan Mackenzie,

who has established a reputation as an archæologist; to Mr. Stevenson, who has made a new departure in Chaucerian study; and to Miss Mary Hamilton's treatise on incubation, as notable results of the Carnegie endowment. Dr. Dobbie says that, with few exceptions, the beneficiaries have fully justified their selection; the memoirs of their researches form no inconsiderable part of the literature of the past five years. Mr. Carnegie cannot but feel gratified by this universal opinion that his endowment of research has been, and still is, bringing forth so rich a harvest. In an appendix to the report a summary of the second quinquennial distribution (October, 1908—September, 1913) in aid of teaching is given. A sum of £40,000 anually is available. It is proposed to continue the library grant of £1,000 to each University; St. Andrews and Dundee £1,000 to each University; St. Andrews and Dundee are to get £10,000 for the equipment of the department of electrical engineering, and £500 for the pathological department. Lectureships on Economics, Geology, and History are to be endowed (£5,000 each). Glasgow has been awarded £13,500 to clear off debt on buildings, etc., in the Medical department, a professorship for Mesontile Low and lectureships on English of Mercantile Law, and lectureships on English, French, German, and Bacteriology are to be endowed (£26,500 in all). Contributions are also to be made to the West of Scotland Technical School, the Agricultural College, and Anderson's College Medical School. In Aberdeen no grants are being made for permanent equipment. Lectureships in Education, German, Constitutional Law, and History are being endowed. A sum of  $\pounds_{2,000}$  is granted to the North of Scotland Technical College. In Edinburgh grants in aid of permanent equipment are made to the Physics department, library, and anatomical museum; £4,000 a year is asked for to be set aside with the Currie Foundation of £17,000 to form a Lectureship Endowment Fund of £37,000; £13,000 is set aside to meet extensions of History. Grants are also made to the Heriot Watt College, to the School of Medicine of the Royal Colleges (£250), School (£250). and to the Women's Extra-Mural

BRITISH MEDICAL ASSOCIATION.—The Spring meeting of the Edinburgh and other Scottish branches was held in the Royal Infirmary on February 26th, and was attended by a large gathering of members. In the Museum a number of interesting exhibits were shown, and, as was the case last year, Dr. Cranston Low's series of casts of skin diseases attracted much attention by the fidelity with which he reproduced Nature. Patients were demonstrated at the clinical meeting by Drs. Chalmers Watson, Low, Farquharson, Cairshill, Byrom Bramwell, Gardener, Edwin Bramwell, Sinclair, Fordyce, Bruce, and by Messrs. Cotterill, Stiles, Caird, Dowden, Chiene, Stutthers, Wallace, Miles, and Scot-Skirving. Demonstrations of venereal diseases, eye cases, surgical out-patients, physical treatment of disease, and electro-therapeutics were also given by Mr. Miles, Dr. Mackay, Mr. Dowden, Dr. Webster, and Dr. Dawson Turner. In the evening the members dined together, the meeting being generally regarded as having been a very successful one.

#### BELFAST

BELFAST MATERNITY HOSPITAL.-The 115th annual meeting of this old charity was held last week, when Dr. Osborne, on behalf of the medical staff, read a report of increasing work on all sides. The new hospital, only opened some four or five years, is already becoming too cramped for the work, and an extension is talked of. The intern patients last year numbered 488, an increase of 110 over the previous year; there were eight maternal deaths, but in each case the patient was admitted in an almost hopeless condition. The extern cases numbered 416, and entailed 2,261 visits.. Sympathetic reference was made to the great loss sustained by the hospital in the death of Dr. Sydney Brice Smyth last summer.

SOCIETY FOR PROVIDING NURSES FOR THE SICK POOR. The annual meeting of this most excellent Society was held last week, and the report showed how finely the work is appreciated. The total number of patients nursed last year was 1,386, of whom 640 were sent by

doctors, including 43 cases where the nurses attended to assist at operations. The nine nurses employed paid no less than 35,800 visits. The work of these nurses does a great deal to relieve the congestion of the number of departments of the hospitals, as an enormous number of dressings of burns, etc., are done daily by them, which would otherwise go to hospital. The ladies who superintend the work of the nurses, and who are personally familiar with the cases, are probably the wisest and most discriminating almoners in the city: they see the home life of the people, and are not humbugged so often as clergymen are, so that the funds which they administer for special help in needy cases are most satisfactorily applied.

#### LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE NEWSPAPER PRESS AND QUACKERY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In his letter on this subject in your columns of February 17th, Mr. Henry Sewill has dealt chiefly with the evils resulting from the use of "indigestion cures" and "sham tonics." Every word he says is true, and there is no doubt about the greedy connivance of the titled (although not for that ennobled) newspaper proprietors who batten with swindlers upon the public credulity. The old saying, populus vult accipi, is now a recognised principle of trade, and a dozen noblemen of recent creation could be mentioned whose fortunes have been entirely derived from intelligent (i.e., impudent and cynical) advertising, the proceeds of which have enabled them to purchase their new dignities. All this, however, is the natural result of scientific evolution, of the application of psychology to trade, and is an example of the survival (the success) of the fittest, that is to say, of the cleverest.

One cannot withstand evolution, and restrictive legislation as suggested by your correspondent is not likely to be obtained if it interferes with such immense vested interests. Medical men would do better, moreover, than to count upon Royal Commissions and to remember the fons et origo of charlatanism is in the profession itself—in the practice of administering unnecessary medicines in the form of placebos, and of allowing patients to believe that the results, due to hygienic measures, employed concurrently with bogus medicines, are the effect of the imaginary remedies swallowed. How can we blame the public for believing in quacks after educating them in the doctrine that post is always propter hoc, and for supposing that an improvement which follows the taking of some advertised nostrum is really the result of the same? Further, is it logical to denounce with such acrimony the cures of Christian scientists, when we reflect that we have taught them to believe that consequences in medical practice are always the effects of the apparent causes—that is of the drugs administered. To eradicate popular superstitions concerning therapeutics, let us begin by reforming

medical ethics.

There is, however, one special category of quack medicines, the proprietors of which constantly exceed the limits of applied psychology and do not hesitate to apply fraudulent lying, and deception, to further the sale of their pernicious wares. I allude to many of the advertisers of cures for drug and alcohol addiction. A scandal of this kind, which was bolstered up by several dignitaries of the Church, and which was so public-spiritedly exposed, and at considerable

expense by yourselves, will no doubt be still fresh in the memories of many of your readers.

In looking over my cases, I find that most victims of the morphia habit have had their addiction prolonged and hope of ultimate recovery destroyed by the use of advertised cures. If the medicines sold, generally at the most extortionate prices, merely consisted of coloured water, as in the case exposed by yourselves, it would not so much matter; but the almost universal policy adopted by the scoundrels

who exploit these specifics is to give the purchaser in a disguised form the very drug they profess to enable him to suppress. This dodge is practised everywhere. An American gentleman, who afterwards became my patient, had come to Europe with a supply of a well-known remedy for which, believing in the statements of the clerical certifiers to its efficacy, he had paid the sum of \$100. Becoming ultimately suspicious, he had the contents of the numbered bottles analysed, and they were found to contain successively

decreasing quantities of morphia.

Another of my patients, a French scientist who was foolish enough to be tempted by a German prospectus, sent for the medicine advertised, but, recognising the nature of the fraud, he wrote to the proprietor taxing him with his deception. Receiving no reply, he took the train to Dusseldorf, intending to denounce the imposture to the authorities. This, however, had already been done, and the business stopped by the police. "They manage," he wrote to me, "these things better in Germany." He had, I should explain, been a few months before one of the innumerable victims, many of whose lives have been ruined by the substitution for morphia of heroin, which, thanks to the supineness of the French police, had been advertised extensively and sold under a pseudonym as a certain cure for morphinism. It is scarcely necessary to point out that to substitute heroin for morphia is about the same thing as replacing wine by brandy or whisky.

In England matters are perhaps worse still. The proprietors of quack medicines are not merely tolerated; a recent trial has shown that they can rely on the encouragement and protection of the law, and that it sometimes costs dear to examine too closely, or at any rate to criticise, the doings of unqualified empirics. It is for this reason that I do not specify more particularly the frauds I am alluding to. I will only say that whenever a drug cure advertised in the papers and magazines is recommended by the ministers of religion, they may almost surely be suspected of

interested complicity.

Many a needy clergyman only manages to make ends meet by receiving paying guests, and a well-known medical practitioner, who is at the same time a Justice of the Peace, gave me recently an amusing account of the tippling that goes on in the public-houses of his village amongst the ex-drunks resident in a certain rectory, and which is patent to all but the parson, who certifies regularly, no doubt in perfect good faith, to their salvation, and so obtains a constant succession of clients from the organisers of the cure with which he is associated.

MR BERNARD SHAW AMONG THE DOCTORS.

I am, Sir, yours truly, OSCAR JENNINGS.

Paris, February 24th, 1909.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. Sir,—It is never too late to mend; and it is pleasant to see that Mr. Bernard Shaw has come out with an address to doctors, on the whole good-natured, and "showing more pity than contempt for natured, and "snowing more pity than contempt for the unfortunate medical men who struggle to make a decent living in poor neighbourhoods." As one of the latter class, I am sorry Mr. Shaw did not begin earlier. I am sorry for the sake of the poor and am sorry for myself. Mr. Shaw, whatever he is now, was until lately an anti-vaccinator, an anti-vivisector, and an anti-bacteriologist. He was engaged actively in backing up the bands of fanatics who devote their lives to the depreciation of science and to the disparagement of its representatives in the medical pro-To what harm these things lead is only fession. known to practitioners among the poor. Distrust of the profession drives the simple and ignorant into the hands of quacks; leads them to rely upon fraudulent nostrums, and to spend £3,000,000 annually upon this trash. This does not hurt the practitioner from the sordid point of view. Of the numbers of people with maladies, aggravated or created by quackery, a vast number pass, sooner or later, into the hands of qualified men; and so money that would not otherwise be earned is put into their pockets. I have just seen a case in point. An old patient, suffering from habitual

constipation, easily controllable by simple methods, has been dosing himself for many months with one of the most largely advertised pills of the day. It is composed, as most of us know, of aloes, ginger, and soap; and is warranted to cure a score of distinct diseases, besides "indigestion." The aloes, in increase. diseases, besides indigestion. It alous, indigestions doses, having originated piles, has now led to formation of a rectal abscess and fistula. I am going to operate, and I shall get a fee of a few guineas entirely through the effect of quackery. Like every practitioner among the poor, I am constantly seeing cases in which life might have been indefinitely prolonged, but which have run on to a stage in which death is inevitable owing to reliance having been placed upon fraudulent nostrums of one kind or another. The people know nothing about the struc-ture of their bodies, and their education in medical matters is almost entirely derived from the puffs which fill the columns of the cheap newspaper press. They nii the columns of the cheap newspaper press. They look upon diseases, or the symptoms they mistake for disease, as distinct entities to be driven out of the body by specific antidotes. Poor patients are unwilling to submit to examination, to scientific investigation of their maladies. They demand "something to do them good," something "to cure" the complaint which they themselves have diagnosed and named with the aid of the quack advertisements which they have studied. The practitioner among the poor is dragged down in his practice to the level of his ignorant patients; often to the moral situation of the meanest of petty business men. It is within the power of Mr. Bernard Shaw to do at least something by his teachings to improve this state of things; let us hope that his new departure implies a promise to do so.

I am, Sir, yours truly,

A Poor Practitioner.

London, N., February 26th, 1909.

THE CENTRAL MIDWIVES BOARD AND SEPSIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The explanations offered by Dr. Ward Cousins and "Obstetrician" do not seem to me to put the objectionable regulation of the Central Midwives Board in any better light. Neither of them deny that the best teaching of modern midwifery regards vaginal examinations as a source of danger. It is doubtful whether it is possible, as Dr. Ward Cousins suggests, for a woman to gain "by internal and external examinations a practical knowledge without any risk to the patients." At any rate, the net result is that pupil midwives will learn from the regulations enforced on them that they should make repeated vaginal examinations, and if they read Dr. Ward Cousins' letter they will further learn that they can do this "without any risk to her patients." Encouraged to get into habit of making vaginal examinations, they are not likely to give up the habit, when they cease to be pupils and become certified midwives. I am, Sir, yours truly,
PATHOLOGICAL.

INCONTINENCE OF URINE ASSOCIATED WITH EPISPADIAS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I regret that my attention has only recently been drawn to the kind letter of "A London Surgeon," which appeared in your issue of February 3rd. Otherwhich appeared in your issue of repruary 3rd. Otherwise I should have sent an earlier reply to his inquiries concerning my account of the operation in THE MEDICAL PRESS AND CIRCULAR for January 27th.

There was not "much difficulty in separating the neck of the bladder and the short urethra from the public bones, and from their lateral attachments."

By going slowly and keeping close to the pubic bones and to the lateral walls of the small pelvis, the risk of injuring the neck of the bladder and the muscular tissues at the side was avoided. I had to rest awhile until the free venous bleeding had been arrested by gauze packing.
As regards the unfortunate need for changing the

obstructed small catheter, after attempts to make it

pervious had failed, there was no great trouble in introducing another one.

The new rubber catheter was well stretched over a carefully moulded stilette, and passed immediately after the other catheter had been withdrawn. The shortness of the urethra made it easy to ascertain the exact direction, when the stilette was removed, and the catheter was thus allowed to resume its natural shape, the latter fitted comfortably.

I am, Sir, yours truly,

R. P. ROWLANDS.

Queen Anne Street.

OXYGEN IN SPORT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—There is no occasion for Mr. Oscar Jennings to write so brusque a letter. Twenty-five years ago W. George, the famous runner, and holder of the mile record, tried oxygen, a fact which I published six months ago, so soon as I learnt it from Mr. George. months ago, so soon as I learnt it from Mr. George. No doubt many others tried oxygen when it was first introduced. Mr. Jennings will find exact determinations of the pulse, blood pressure, respiratory volume, etc., in my papers, published in the Journal of Physiology, and he should not be so rash as to assert that observations made by me "are totally wanting in physiological control." I shall be glad to see the account of Mr. Jennings' observations, which, published as they were in a weekly journal, have either escaped or not received the attention of all those who have carried out fundamental researches on the respirahave carried out fundamental researches on the respiranave carried out fundamental researches on the respira-tion. I would point out that the sphygmograph is not an instrument which can be used to measure tension of the left heart, and that Mr. Jennings' explanation of the action of oxygen is wholly wrong. "It does not restore wind at once by rendering the lung adequate to the extraordinary demand on it." I am indifferent whether athletes use oxygen to break records or notbreaking records is a foolish pursuit, and not sport in the true sense. What I have ascertained is that oxygen inhalation affords a simple and powerful method of relieving the fatigue of the heart which follows extreme muscular effort, and that oxygen and exercise can be used as a valuable method of treatment. able method of mounts of truly,

I am, Sir, yours truly,

LEONARD HILL.

#### AN APPEAL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—I write to ask you to open a subscription list for Dr. William Winslow, who, having acted for 47 years as Dispensary Medical Officer of Gowna Dispensary District, County Cavan, Ireland, was compelled to resign in October last year, at the age of 69 years, owing to ill-health, chiefly the result of hard

The facts are as follows:-

The district is a large one, about 14 to 18 miles, with a lake in the centre, which makes it very hard to work. It consists mostly of bog land, and therefore, needless to say, yielded very little indeed in private fees, and mostly required two horses to work

it properly.
When Dr. Winslow was first appointed his salary was £80 a year, this was after a time raised to £100, and subsequently to £120. On this salary, plus £16 as M.O.H., and about £20 from vaccination and registration fees, he kept the two horses necessary to work the processor of work the practice, reared a family of ten children and work the practice, reared a raminy of ten children and gave them a sound education. It should also be remembered that it is only during the last few years that Dispensary Medical Officers were allowed fees for a locum while on their holiday.

Dr. Winslow's willing readiness at any hour of the day or night to answer the calls of those who required him was proverbial throughout the entire district.

Last spring he contracted influenza, followed by heart trouble, and although after a sick-leave rest he made every attempt to continue to work the district in which he had spent his life and energies, he was compelled to resign.

Let me add that during all these years there never was any question that Dr. Winslow had done his

work other than to the perfect satisfaction of the Guardians.

Now note what happened: this district is under the control of the Granard Board of Guardians; this body duly met and awarded a pension of £80 a year. It appears the maximum they could have allowed is some £92 odd. The Local Government Board, who seemed wishful that the full superannuation should be granted, wrote to the Guardians and pointed out that at the passing of the 1898 Local Government Act, Dr. Winslow was 60 years of age, and entitled to look for a pension then, and asked them to reconsider their decision. This the Guardians refused to do. The Local Government Board then raised some technical point to the effect that sufficient notice had not been given and requested the Guardians to bring the matter up again. This the Guardians had to do, and meeting on February 15th, reduced the superannuation of £80, to which they had already agreed, to £60!

Although the resignation took place last October, no

pension money has been received yet. This has been a source of great worry to him. On this £60 Dr. Winslow has to keep himself (an invalid), his wife, and one unmaried daughter. All his other children, with the exception of one, who fell in the South African War, have heavy financial responsibilities of their own; all have families except one, and one is a

widow with three children.

Surely it is not the wish of the Profession generally that one of its members, after so many years of hard and good work, should, through the ignorance or ingratitude of those whom he faithfully served, and through no fault of his own, be left in old age and enfeebled health to drag out the closing scene of his life in anxiety and want.

I appeal, therefore, to the Profession, and especially to Irish medical men, who understand perhaps better than others the injustice and the hardships of the Irish Poor-law medical system, to subscribe to a fund for his benefit, crossing cheques, "Winslow Fund," and making them payable to:

Yours faithfully,

ARTHUR GREENE, M.A., M.D., F.R.C.S.I.

4, Theatre Street, Norwich, Feb. 20th, 1909.

[We shall be glad to give any assistance in our power to any movement to help Dr. Winslow in this case. We would, however, suggest to Dr. Greene that he should form a small committee of men whose names would carry weight both in England and Ireland, as by so doing he would probably collect more money. We also suggest that he should bring the case to the notice of the Irish Medical Association, of which we understand Dr. Winslow has been a member for many vears.—ED.]

#### SCHOOL DISINFECTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—I should be glad if you would allow me space for comment on a portion of a paper by Dr H. Meredith Richards, Medical Officer of Health for

( roydon, which appeared in a recent issue of a medical

contemporary.

Dealing with the subject of disinfection, Dr. Richards says:—"I sincerely hope that medical inspectors will not play into the hands of the wily manufacturer of germicides by suggesting the disinfection of premises when the bacteriological examination of a class or the exclusion of individual children is really indicated. Nor, I trust, will they vaunt the success of their favourite germicide in stamping out an epidemic which has already attacked the whole of the susceptible population exposed to infection."

The only inference to be drawn from these remarks is that the routine disinfection of schools, which of recent years has been urged in many quarters, is in reality a trade device for the sale of particular germisides. If Dr. Richards is in possession of information which warrants such an implication, he is, of course, perfectly justified in warning his brother officials; but, in the absence of such information, I should like to remind him that the mere fact that the principle of disinfection is advocated by manufacturers of disinfectants is not in itself sufficient to prove that the process is of no value as an aid to the prevention of

epidemic disease in elementary schools.

A paper by Dr. A. D. Edwards, Medical Officer of A paper by Dr. A. D. Edwards, Medical Officer of Schools, Bournemouth, which appeared in the *British Medical Journal* of February 13th, provides a striking commentary on Dr. Richards' contention that disease is spread by infected persons rather than by infected things. Dr. Edwards states that he collected all the slate pencils of a class in one of the schools, "made stroke cultures in a few tubes and the schools of the schools." stroke cultures in a few tubes, and the borough bacteriologist reported the presence of the Klebs-Loeffler bacillus in the growth." Among other preventive measures Dr. Edwards recommends the routine disinfection of the schools.

It seems scarcely probable that various medical men and public bodies have combined to "play into the hands of the wily manufacturer of germicides"; the more likely explanation of their advocacy of disinfection is that they recognise in it a practical preventive measure. No one, I should imagine, has ever contended that disinfection of the elementary schools, of itself, would prove sufficient to eradicate infectious disease. That there is much to be said in its favour, however, is shown by the expressed opinions of the authorities I have quoted, and in view of the fact that the measures at present at the disposal of the authorities have not achieved any marked diminution of school epidemics, it seems to me personally that hostility to the systematic use of disinfection is unwise and inimical to the interests of the community.

I am, Sir, yours truly, J. T. AINSLIE WALKER.

February 28th, 1909.

#### OBITUARY.

CHARLES ROUTH, M.D.LOND., M.R.C.P.LOND.

WE regret to announce the death of Dr. Charles

WE regret to announce the death of Dr. Charles Henry Felix Routh on the arst ult., at his residence in Montagu Square, London, W., at the age of 87. Dr. Routh was the eldest surviving son of Commissary-General Sir Randolph Routh. In 1843 he became a member of the Royal College of Surgeons, whilst a year later he took the M.B. and in 1845 the M.D. degrees of London University. He was also a member of the Royal College of Physicians. He received his medical education at University College Hospital, Paris, and Vienna. Dr. Routh held many appointments, including Consulting Physician for Diseases of Women at the North London Hospital, the Consump-Women at the North London Hospital, the Consumption and Samaritan Hospitals, and the Cripples Homes for boys and girls. He was a Physician at St. Pancras Royal Dispensary, and a corresponding Fellow of both the Royal Academy of Madrid and the Academy of Pesth.

For over half a century he contributed articles on infant feeding, cancer, and other subjects to the London medical journals, the *British Gynacological Journal*, and other publications. Dr. Amand J. McC. Routh, Obstetric Physician to Charing Cross Hospital, is his son.

### DR, ROBERT HENRY COALL, L.R.C.S., L.R.C.P, Edin.

L.R.C.P.EDIN.

By a sad coincidence, this gentleman died at Cannes on his 50th birthday. Son of the late Talbot Coall, of Kingstown, Co. Dublin, he was born on February 20th, 1859, his death occurring on February 20th, 1909. He was engaged for some years past in a somewhat extensive practice in Brook Street, London, but latterly developed tuberculosis, and was residing for the time being at Cannes, where his health improved so much that a few days before his death he was making preparations to return to London from was making preparations to return to London from the Riviera, when an acute attack of hæmoptysis supervened, to which he succumbed, as before stated. on the 20th ult. Deceased was medically educated at Carmichael School, Dublin, whence he took the double qualification of Edinburgh in 1884. He was unmarried, but his genial character and happy dispo-sition endeared him to all with whom he was brought

in contact, and at his funeral at Cannes on Thursday last many leading members of the English community followed him to his last resting-place.

SIR JOHN WATT REID, K.C.B., M.D., LL.D.

WE regret to record the death of Sir John Watt Reid, at the age of 86. He was honorary physician

to the King and to Queen Victoria

Sir John Reid was the son of Dr. John Watt Reid, R.N., and entered the Royal Navy in 1845. In 1880 he became Director-General of the Medical Department of the Navy, which post he held until 1888, when he retired. He served in the Russian war in the Black Sea, 1854-55; in the China war, 1857-59; and in the Sea, 1854-55; in the China war, 1857-59; and in the Ashanti campaign, 1874. For his services in the last-named campaign he was mentioned in despatches, promoted, and received the medal. He was made a K.C.B. in November, 1882.

Sir John Reid was educated at Edinburgh, and obtained the Doctor of Laws and Doctor of Medicine

degrees from the Universities of Edinburgh and Aberdeen respectively, and became a licentiate of the Royal College of Surgeons in 1844. He married, in 1863, Georgina, a daughter of Mr. C. S. Hill, of Halifax,

Nova Scotia.

#### REVIEWS OF BOOKS.

A SYSTEM OF SYPHILIS. (a)

A SYSTEM OF SYPHILIS. (a)

The second volume of this work contains: (1) "The Surgery of Syphilis," by D'Arcy Power; (2) "The Treatment of Syphilis," by Colonel F. J. Lambkin, R.A.M.C.; (3) "An Outbreak of Syphilis in a Virgin Soil," by Colonel F. J. Lambkin, R.A.M.C.; and (4) "Syphilis in Obstetrics," by Dr. W. J. Gow.

(1) Mr. D'Arcy Power in his first chapter gives a short, but very lucid and convincing historical account of the origin of syphilis in Europe, showing plainly that the disease was brought from America by Columbus, disseminated over Spain and Italy, carried to France by the troops of Charles VIII. after their sojourn in Naples, and finally brought to England by way of Bordeaux in 1497. He takes his readers on to the discovery of the spirochæta pallida, and theorises very ably on the connections between syphilis and cancer and syphilis and tuberculosis. The second chapter deals with syphilitic diseases of the bores, and does not teach us anything very new; in fact, we and does not teach us anything very new; in fact, we should have been pleased if the differential diagnosis between syphilitic and tuberculous diseases of the bones had been more elucidated. A similar remark also applies to the next chapter with reference to gonorrhoeal and syphilitic affections of joints. Some interesting points are here considered on Charcot's disease and on symmetrical serous synovitis. Syphilitic diseases of muscles, tendons, and bursæ and teeth are described shortly in the next two chapters. The following chapter dealing with the mouth and tongue is well worthy of careful perusal; leucoplakia of the tongue, especially, with its treatment is excellently explained, together with the fissures to which this disease often gives rise. In dealing with the rectum, Mr. D'Arcy Power confines himself to generalities in a subject which we should have thought would have given him an extensive scope for teaching, but he evidently will not trench on ground which is to be taken by others in future volumes of this work. In the chapter on the urethra and prostate, we are confronted again with the disadvantage of a multiplicity of authors writing for the same work, for Mr. Power, in authors writing for the same work, for Mr. Power, in speaking of chancres of the meatus, refers us back to their description in Vol. I., by Colonel Lambkin, which, on reference, consists of about eight lines; we should have thought Mr. Power could have given us many useful hints with reference to the difficulty of diagnosis of the innocent-looking sores met with in this citation. This is brought still more forcible to this situation. This is brought still more forcibly to

(a) "A System of Syphilis." Edited by D'Arcy Power, M.B., F.R.C.S., and J. Keogh Murphy, M.D., M.C., F.R.C.S. Vol. II. Pp. vill. and 387. Oxford University Press: H. Frowde. London: Hodder

our notice by the able words on the differential diagnosis between tuberculous, sarcomatous and syphilitic testicle given in the next chapter. All that is known on gummatous inflammation of the mammary gland and on syphilitic goftre is ably set forth. Mr. Power on syphilitic goftre is ably set forth. Mr. Power devotes eighty pages to a really admirable treatise on the treatment of syphilis. He explains the various methods, and sets forth the advantages and disadvantages of each in a scientific and unbiassed manner. vantages of each in a scientific and unbiassed manner.

(2) The next seventy pages are devoted to the same subject, but from the pen of Colonel Lambkin, who necessarily has to cover a good deal of the same ground as Mr. Power; Colonel Lambkin, however, shows a very decided leaning towards treatment by intra-muscular injections with the insoluble salts of mercury.

(3) Colonel Lambkin then gives a very instructive and interesting account of "An Outbreak of Syphilis in a Virgin Soil," culled from notes on syphilis in the Uganda Protectorate. It seems sad to syphilis in the Uganda Protectorate. It seems sad to chronicle that the causation of the outbreak, according to Colonel Lambkin, had a twofold origin: (1) "The introduction of Christianity and the consequent abandonment of polygamy and of the old restrictions of the old restrictions of the old restriction of the old restrictio on the liberty of the women." (2) "The abolition of the punishments formerly meted out among the tribes for all immoral offences committed by either sex. for all immoral offences committed by either sex." This last we may regard as due to the march of civilisation. (4) The last chapter of this volume consists of an excellent treatise on "Syphilis in Obstetrics," from the pen of Dr. W. J. Gow, who ably discusses the vexed questions of conceptional, infantile and neonatal syphilis, together with Colles' and Profeta's laws; he also gives a short and concise account of the morbid anatomy af the syphilitic fœtus, of its various organs and of the placenta. The illustrations, which are all placed together at the end of the book, are excellent; but we still cannot help thinking that it would be more but we still cannot help thinking that it would be more convenient to the reader if they were each inserted opposite the respective page in which reference is made to them.

#### DISEASES OF THE NOSE AND THROAT. (a)

THE third edition of this well-known manual has appeared, having undergone a thorough revision, while the general characteristics of the former editions have been adhered to. As will be remembered, the second edition appeared under the joint authorship of Dr. de Havilland Hall and Mr. Herbert Tilley, but for this edition Mr. Tilley alone is responsible.

A new feature in the book is one that appeals to the fancy of the reviewer. He refers to the short anatomical description of the nasal cavities and the

accessory sinuses which, with capital illustrations, gives a very clear idea of the parts dealt with. The general trend of the book is essentially practical, and we thus have presented to the majority of readers a book which will be found interesting to read and reliable for reference when in doubt or difficulty.

The operations are very clearly described, and with the help of such good ilustrations there is no difficulty in following the author's ideas. At the end there is a formulary of prescriptions which will be helpful. It may be stated that Mr. Tilley's manual is one of the best arranged works of its kind which we have read, and will amply repay those who read it.

#### Medical News in Brief.

Birmingham and Midland Counties Sanatorium.

THE Lord Mayor of Birmingham presided on February 24th at the annual meeting of the Birmingham and Midland Counties Sanatorium. In his speech he remarked that he could only say with regard to this particular Society that there was not one more worthy of the support and admiration of the whole city. Its operations were not as large as some, but its work was

<sup>(</sup>a) "Diseases of the Nose and Throat," By Herbert Tilley, B.S. Lond., F.R.C.S. Eng., Surgeon to the Ear and Throat Department, University College Hospital, &c. Five hundred and twenty-four pages, with 126 illustrations. London: H. K. Lewis. Price 14s.

extremely valuable, and he was perfectly sure that it would be very much missed if by any unfortunate chance it came to an untimely end. It was an old Society, and he regarded it very much as a model Society. It was started just at the right time, and when the idea of sanatoria was almost unknown. In recent years the precautions taken with regard to public health had had the effect of reducing illness of all kinds, and they might hope that this would go on extending in future, so that they need not look to the indefinite extension of hospitals and sanatoria. There was not the slightest chance of such institutions being abolished at any time, certainly not in our time, and while they were in existence it behoved us to keep them in a state of efficiency.

The Lord Mayor was elected President for the ensuing year.

The year, said the committee in their report, had been one of increased usefulness, the number of patients having been the largest in the history of the sanatorium, namely, 1,655, with an average stay of 17.8 days, as compared with 1,598 patients in 1907, with a similar average stay. The increase in the work of the institution had brought with it an increased expenditure, and although the general income had been well maintained as compared with former years, yet it was with regret the committee had to report an adverse balance upon the year's accounts of £170 11s. 6d. They earnestly appealed for a substantial increase in the number of annual subscribers to ensure that the effi-ciency of the institution should be in no degree impaired.

#### Serious Outbreak of Typhold Fever at Kirkburton.

A serious outbreak of typhoid fever has occurred at Kirkburton, near Huddersfield. On November 21st last an isolation hospital erected near the railway station was opened for the treatment of patients suffering from infectious diseases other than small-pox, and a resident of an adjacent township, who was suffering from or an adjacent township, who was suffering from typhoid fever, was taken to the hospital a few weeks ago. A fortnight ago another person residing in Foresters' Row, Kirkburton, which is situated at the foot of a steep hillside almost immediately below the hospital, was found to be suffering from typhoid, and was removed to the hospital. A couple of days later the disease appeared in houses at Zion Hill, near to and on the same level as Foresters' Row. Other cases subsequently occurred at Zion Hill, and the patients were removed to the hospital, until there were six Kirkburton patients all suffering from typhoid. A girl of 13 died in the hospital on Wednesday, and on February 25th two more patients were admitted. There is now no more accommodation for typhoid fever cases, and one patient is being treated at home.

#### The Middlesex Hespital.

THE claims of the Middlesex Hospital to increased financial assistance were enforced at the annual meeting of the Court of Governors held on February 25th, under the presidency of Mr. Pearce Gould, the Senior Surgeon.

Lord Cheylesmore, who moved the adoption of the report, called attention to the fact that the total number of in-patients treated in the past year was 4,313, being an increase of 395 on the figures for the previous year, while in the out-patient department the number of new patients relieved was greater by 1,627, the total being 49.224. But the financial position had never been so serious during the twenty years he had been connected with the institution. The great loss was in bequests. In the last three years the average receipts from this source had fallen by one-half, and he failed to understand why the hospital did not get more generous support. Dr. Pasteur seconded the motion: The Chairman said that all round there was evidence of increased activity and extended means of doing the proper work of a hospital, but a more general interest and financial support were lacking. The motion, which was agreed to, also included the acceptance of a report on the administration of the Cancer Charity, respecting which Dr. Lazarus-Barlow gave a brief account of the work done in the Cancer Research Laboratories since their opening in 1900. He is the director of these labora-

Referring to investigations upon heredity in cancer, he said that examination of the records of 8,000 cancer cases of which the hospital had notes showed that there was no evidence that the disease was inherited. From the point of view of life assurance and of allaying a general fear, this work was of great public utility. The annual reports issued from the laboratories were full of information that was valuable to workers on cancer, and the information was as reliable as he and his assistants could make it. One great difficulty he had to contend with was the natural impatience of the public at the slow rate of progress. But the cancer question was bound up with the laws of growth, and though growth of an infant to manhood had been known for untold years, yet practically nothing was known as to the laws that governed that growth. So with cancer.

#### Humidity and Ventilation in Cotton Weaving Sheds.

THE report of the Departmental Committee on Humidity and Ventilation in Cotton Weaving Sheds Humidity and Ventilation in Cotton Weaving Sheds was issued on February 26th as a Parliamentary paper. The Committee, which was appointed in November, 1907, consisted of Commander Sir Hamilton Freer-Smith, R.N. (chairman), Mr. Joseph Cross, Mr. Henry Higson, Mr. T. Roberts, Mr. D. J. Shackleton, M.P., Professor James Lorrain Smith, Mr. Wilkinson Hartley, and Mr. Fred Thomas. Mr. Duncan R. Wilson acted as secretary. The report is signed by all the members of the committee except Mr. Higson, who died before the inquiry was concluded. died before the inquiry was concluded.

After submitting 13 recommendations of a technical character, the committee state in conclusion:—
"It is anticipated by the committee that their recommendations in regard to the standard of ventilation will by some be considered retrograde. In their decision they have been influenced by the evidence of eminent physiologists and by the personal experiences of the vast number of operatives immediately concerned, and they are of opinion that, although it is desirable to approximate as nearly as possible to natural conditions, yet when trade exigencies do not permit of this, it is better to have a standard capable of doing much good rather than no standard at all. They have further borne in mind that the interests of one of our largest industries should be considered and that manufacturers should not be called upon to maintain ventilating plant at enormous expense, unless it can be clearly shown that this is necessary for the well-being of the workers. In certain branches of the textile trade alone has a standard of ventilation been fixed, and it is perfectly well known that throughout the country in indoor occupations, especially in winter, the standard now proposed is often enormously exceeded.'

#### Medical Sickness and Accident Society.

THE usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 429 Strand, London, W.C., on 19th ult.

There were present: Dr. de Havilland-Hall, in the chair; Dr. M. Greenwood, Dr. J. Pickett, Dr. J. Brindley James, Dr. St. Clair B. Shadwell, Dr. W. A. Dingle, Dr. W. G. Dickinson, Dr. Frederick S. Palmer, Dr. J. W. Hunt, Mr. J. F. Colyer, Dr. W. Knowsley, Sibley, Mr. F. S. Edwards, Mr. Edward Bartlett, and Dr. J. B. Ball.

The presenting of the Society during the month of

The operations of the Society during the month of January have been unusually successful. The claims have been moderate in number and for the most part of short duration, and as more than one of the chronic cases have been removed by death, the sickness experienced has been under the expectations. It has been resolved that the next annual general meeting of the Society shall be held at the rooms of the or the Society shall be held at the rooms of the Medical Society of London, 11 Chandos Street, Cavendish Square, London, W., on Thursday, May 27th, at 4.30 p.m., and a very favourable report may be expected by the members.

Prospectuses and all further information on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society as Changest Land London.

and Accident Society, 33 Chancery Lane, London, W.C.

#### NOTICES TO CORRESPONDENTS. &c.

COMMESSIONDENTS requiring a reply in this column are particularly requested to make use of a Distinctive Signature or Initial, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

BUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January lat and July lat respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker. Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

#### ADVERTICEMENTS.

FOR OME INSERTION:—Whole Page, 25; Half Page, 22 10s.; Quarter Page, 215s.; One-eighth, 12s. 6d.
The following reductions are made for a series:—Whole Page, 13 insertions, at 23 10s.; 26 at 23 3s.; 53 insertions at 23, and pro rata for smaller spaces.
Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

#### PICTURES FOR OXO CUSTOMERS.

IN return for a certain number of Oxo coupons, it is open to purchasers of that article to obtain one or more fine coloured reproductions of Count Aldin's famous sporting pictures. Any. readers who may wish to obtain further particulars, can obtain the desired information on application to the Oxo Picture Office, 4. Lloyd's Avenue, London. E.C.

PERPLEXED.—The "dark room"—that is to say, confining a patient suffering from some disease of the eye, or after an operation upon an eye, to a room from which the light is excluded, is a mediaval superstition, comparable to the horrors of the Inquisition—which the enlightenment of science has dispelled as being an unnecessary feature of the treatment.

#### SIR J. BATTY TUKE AND THE PAINTER.

SIR J. BATTY TUKE AND THE PAINTER.

SIR JOHN BATTY TUKE, the well-known member for Edinburgh and St. Andrews Universities, celebrated recently his seventy-third birthday. His speciality is, of course, mental disease, upon which he is one of the greatest English authorities. An amusing story is told of him in this connection which is often repeated in Edinburgh University direles. Sir John is director of a home for the insanc in Edinburgh, and upon one occasion when the woodwork of the home required repainting, he himself delivered the order to the master painter that the work should be carried out. He impressed upon him with great earnestness that the painter who should be sent to do the work must on no account enter into conversation with any of the inmates of the home. Upon the following day Sir John went to see how the work was progressing, and, seeing the workman busily engaged, he asked him casually how many costs of paint he had put on. His question was met with absolute silence. He repeated it a little more sharply. Still no answer was returned. Annoyed at this neglect, Sir John sllowed his indignation to express itself in suitable terms and with such effect that at last the workman turned. "Awa" wi' ye, ye delectious deevil!" he cried, "awa" wi' ye!" And then he added in a gentler tone, "But I'ms sorry for ye a' the same." And then, of course, Sir John Batty Tuke understood. And although the joke was against himself, he always gave high credit to the workman for the humanity he expressed.—"M.A.P."

#### Meetings of the Societies, Tectures, &c.

WEDNESDAY, MARCH 3RD.

ROYAL COLLEGE OF SCHEKONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5 p.m.: Prol. A. Keith: The Mechanism of Respiration in Man. (Hunterlan Lectures.)

ROYAL EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Clinios: 2.30 p.m.: Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meschen); Bye (Mr. R. P. Brooks).

THURBDAY, MARCH 4TH

NORTH-EAST LONDON CLINICAL SOCIETY (Prince of Wales's Hospital, Tottenham, N.).—4.15 p.m. Clinical Cases.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchhedie Street, Edgware Road, W.).—8.30 p.m.: Discussion on the Early Diagnosis and Treatment of Cancer of the Stomach (opened by Dr. W. H. White and Mr. B. G. A. Moynihan).

ROSTORN SOCIETY (20, Hanover Square, W.).—8.15 p.m.: Mr. A. A. C. Swinton: Some Vacuum Tube Phenomens.

ROYAL COLLEGE OF PHYSICIANS OF LONDON (Pall Mall East).—5 p.m.: Dr. R. T. Hewlett: Disinfection and Disinfectants. (Milroy Lectures.)

ROTAL COLLEGE OF PHIBICIANS OF SAME AND ASSESSION OF SAME ASSESSION OF SAME AND ASSESSION OF SAME ASSESS

FRIDAT, MARCH STR.

ROTAL SOCIETY OF MEDICINE (LARTHGOLOGICAL SECTION) (20, Hanover Square, W.).—5 p.m.: Cases, Specimens, etc.: Dr.

Lambert Lack: Telangicotasis with Bpistaxis. Mr. W. Stuart-Low: (1) Thyroid Tumour of the Tongue; (2) Case showing an Unusually Large and Long Tongue. Dr. Donelan: (1) Uvula with Growth on Left Side; (2) Right and Left Rectangular Chisels for Removing Nassl Wall of Maxillary Antrum.

ROYAL SOCIETY OF MEDICINE (SECTION OF AMERIKETICS) (20, Hanover Square, W.).—At 8.30 p.m.: Discussion: On the Treatment of Shock during Amesthesia (opened by Dr. Dudley Buxton).

Buxton).

ROTAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5 p.m.: Prof. A. Keith: The Mechanism of Respiration in Man. (Hunterian Lectures.)

NORTH-EAST LONDON POST GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinic: Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Operations: (Mr. W. Edmunds). Clinics: Medical Out-patient (Dr. A. G. Auld); Eye (Mr. R. P. Brooks). 3 p.m.: Medical Lapatient (Dr. R. M. Leslie). 4.30 p.m.: Lecture: Mr. R. P. Brooks: Types of Keratitis, their Diagnosis and Treatment.

SATURDAY. MARCH 6798

ROTAL SOCIETY OF MEDICINE (OTOLOGICAL SECTION) (20, Han-over Square, W.).—10 a.m.: Paper: Mr. Sydney Scott: A Con-tribution to the Problem of Vertigo. Cases and Specimens-illustrating the subject of Vertigo can be shown at this meeting.

#### Appointments.

BARRETT, W. E., L.R.C.P. and S.Edin., Clinical Assistant to the Samaritan Free Hospital for Women.

Colter. Stanley, M.D., B.S.Lond., M.R.C.P.Lond., Honorary Medical Officer to the Royal Halifax Infirmary.

DENNE, Archibald, M.B., Ch.B., Clinical Assistant to the Samaritan Free Hospital for Women
Fritzer, Isidor, M.R.C.S., L.R.C.P., Clinical Assistant to the Samaritan Free Hospital for Women.

Holmes, Gordon, M.D., B.C., B.A.O.Dub., Assistant Physician to Out-patients at the National Hospital for the Paralysed and Epileptic.

Kinedon, J. R., M.R.C.S., L.R.C.P.Lond., Medical Officer of Health to the Lynn Town Council.

Murison, A. Locan, M.R.C.S., L.R.C.P.Lond., Assistant Surgeon to the Metropolitan Ear, Nose, and Throat Hospital.

POTTER, J. C., M.D.Edin., Surgeon to the Metropolitan Ear., Nose, and Throat Hospital

VENNING, J. A., M.B., B.C.Cantab, Clinical Assistant to the Samaritan Free Hospital for Women.

WILLIAMSON, GEORGE SCOTT, Pathologist to the West Riding Asylum, Wakefield.

#### Bacancies.

Beimullet Union.—Medical Officer. Salary £160 per annum, and £10 a year as Medical Officer of Health with Vaccination and Registration fees. Applications to E. W. Flynn, Clerk of the Union.

a year as Medical Officer of Health with Vaccination and Registration fees. Applications to E. W. Flynn, Clerk of the Union. (See advt.)

County Borough of Tynemouth.—Medical Officer of Health. Salary, 2300 per annum. Applications to E. B. Sharpley, Town Clerk, Town Hall, Tynemouth.

West London Hospital, Hammersmith Road, W.—Pathologist. Salary, 2200 per annum. Applications to B. J. Gilbert, Secretary-Superintendent.

Argyle and Bute Asylum, Londgilphead.—Assistant Medical Officer. Salary, £160 per annum, with board, apartments, and laundry. Applications to the Medical Superintendent. Surrey County Lunatic Asylum, Brookwood, near Woking.—Third Assistant Medical Officer. Salary, £170 per annum, with board, lodging, and leundry. Applications to the Medical Superintendent.

Carlow District Asylum.—Resident Medical Superintendent. Salary, £350 per annum, and allowances valued at £150 per annum. Applications to the Secretary. (See advt.)

Brixton Dispensary, Water Lane, S.W.—Resident Medical Officer. Salary, £150 per annum, with furnished apartments, attendance, coal and gas. Applications to W. Halliday, Secretary. County Borough of Croydon.—Croydon Borough Hospital.—Assistant Resident Medical Officer. Salary, £120 per annum, with board, lodging, and washing at the hospital. Applications to F. C. Lloyd, Town Clerk, Town Hall, Groydon.

#### Births.

BOTT.—On Feb. 28th, at 58 Cambridge Terrace, Hyde Park, London, the wife of Percival G. A. Bott M.B. Lond, F.R.C.S.Ed., of a soc. WILSON.—On Feb. 27th, at The Hollies, Lee Terrace, Blackbeath, the wife (née Mary Mein) of C. Edgar A. Wilson, B.A., M.B., B.Ch. Oxon, of a son.

#### Marriages.

COWAH—DRAPHR.—On Feb. 23rd, at the Parish Church, Comington, Captain James Cowan, R.A.M.C., youngest son of the late John Cowan, Dunadry, Co. Antrim, to Linda Margaret, only daughter of the late 1 homas Draper, Lymm, Cheshire.

#### Beaths.

Amenous.—On Fab. 27th, at Southgate Lodge, Devises, suddenly, of heart failure, Liout-Colonel John Ambrose, R.A.M.O., rethred, aged 83. Norman.—On February 20th, at Guernsey, Bertram, third son of Thomas Norman, M.D., of Orosby, in his 38th year.

## The New Dietetic Preparation.

OVALTINE is a dietetic preparation—in granular powder form—of high thrapeutic value, made of Malt Extract, Fresh Eggs, Milk, and Converted Cocoa, and containing Active Lecithin.

Extremely Nourishing and highly Restorative.

Very Palatable and acceptable to the most delicate stomach.

1. P. P.

Simple to prepare.

The best substitute for Tea, Coffee, &c., and the only preparation of this kind containing Organic Phosphorus (Lecithin).

A powerful Digestive Agent and a Nervine Tonic of the highest order.

## OVALTINE

is the remedy par excellence in Convalescence, Neurasthenia, Faulty Digestion, Malnutrition, Brain Fag, Over Study, and Exhaustion.

Reactly assimilated and particularly adapted for the over-feeding of the Tub reulous. Suitable for infants, youths, adults, and the aged.

OVALTINE is packed in  $4\frac{1}{2}$  oz., 9 oz. and 18 oz. tins. LITERATURE AND SAMPLE FREE TO MEDICAL MEN.

A. WANDER, Ph.D., Manufacturing Chemist 1 Leonard St., City Rd., LONDON, E.C.

# Lemco

is offering to its customers (by arrangement with Thermos, Limited) in exchange for Lemco Weight Coupons, a unique and useful article, viz., the

### Lemco Thermos Flask—FREE.

Full Pint size, the same as sold for 1 Guinea.

Free for Weight Coupons representing 7lbs. Lemco. Customers wishing to obtain a flask sooner may send 5lbs. Weight Coupons and deposit of 7/6 10/The Deposit will be returned on receipt of balance of Coupons. Weight Coupons are under capsule on each jar.

The Lemco Thermos Flask is splendid for keeping Lemco hot through the night, for keeping hot liquid food in the night nursery, and for carrying hot bouillon on the motor. Invaluable for invalid and general use. It will keep its contents steaming hot for 24 hours, or icy cold for many days.

LEMCO is pure, fresh beef, in the most perfectly concentrated form known. No preservatives in Lemco, yet it keeps for any length of time. No added flavouring, yet its pure beef flavour makes it appetising beyond compare. Its high concentration makes Lemco the most economical form of beef sold. Owing to its purity and freedom from fat, invalids can retain it when home-made beef-tea nauseates.

This offer is in force till December 31st, 1909.

Doctors should be careful to prescribe "Lemco"—the distinctive Trade Mark by which the original Liebig Company's Extract of Beef is now sold.

Lemco Bonus Office, 4, Lloyd's Avenue, London, E.C.

# Influenza?

The present mild outbreak of "influenza," in which gastric and intestinal symptoms are prominent, may be combated to a large degree by efficient intestinal antisepsis. These symptoms are indisputably those of fermentation, of bacterial origin. It is not necessary that the influenza organism (Pfeiffer's bacillus) should reach the gastric and upper intestinal regions to effect such troubles, as the devitalising influence, produced generally by the growth of this bacillus in any part of the body, affords free opportunity for the untrammelled activities of certain intestinal organisms which in health remain in a state of inhibition, or at least fail to assume pathogenic powers.

## Cyllin Palatinoids

are accordingly indicated as a direct and reliable preventive measure.

Cyllin Inhelent as an auxiliary agent may be relied upon to supplement the action of Cyllin Palatinoids in the respiratory tubes, more especially the naso-pharynx, pharynx, and upper larynx. To be used pure in special Inhalator.

See Pamphlet entitled "STANDARD CHEMICAL DISINFECTANTS." Copies, tegether with working Samples, seat gratis and postage paid on applying to

Jeyes' Sanitary Compounds Co., Ltd., 64 Cannon Street, London, E.C.

### Xeroform

Powder for wounds; absolutely non-poisonous, non-irritant, sterilisable. Applied to aseptic wounds in a thick layer, Xeroform prevents the dressing adhering to the wound, the

retention of discharge and suppuration along the path of the stitches. In burns, intolerable pain is at once relieved, healing is rapid with very little discharge, and the scar is smooth and delicate. A specific in moist eczema and in chronic ulcers of the leg.

A rapidly curative remedy, relieving pain, in **rheumatic** troubles; to be rubbed into the skin in muscular rheumatism, acute neuralgia, teno-synovitis, rheumatic pleurisy.

Salit is tolerated by the skin undiluted. No secondary actions.

Novargan

Renders possible a powerfully bactericidal treatment of gonorrhea, for, being non-irritant, it may be used in comparatively high concentration.

disinfects the urinary passages by the liberation of Formaldehyde in acid or alkaline urine; it rapidly imparts an acid reaction to the urine, and it has no irritant action on the

digestive canal or the kidneys.

## "P., D. & Co." HYDROGEN PEROXIDE SOLUTION

yields the best results
in surgery and dentistry
by reason of its exceptional purity and stability.

"P., D. & Co." HYDROGEN PEROXIDE SOLUTION conforms to the standard prescribed by the British Pharmacopœia. By its use the surgeon may avoid the disappointment which the notoriously unstable commercial article so frequently engenders.

#### A CONVINCING TEST.

A bottle of "P., D. & Co." HYDROGEN PEROXIDE SOLUTION was stored side by side with one of another brand for seven months. At the end of that period, analysis proved that the former had lost 0.3 per cent. of its strength, whereas the latter had lost 30 per cent.

"P., D. & Co." HYDROGEN PER-OXIDE SOLUTION proves an excellent disinfectant dressing for wounds, sores, etc., and a purifying irrigant of sinuses, fistulæ and abscess cavities.

Suitably diluted, it forms an efficient antiseptic injection (non-poisonous and unirritating) in dysentery, cystitis and urethritis, and for urethral, vaginal and rectal infections of various kinds.

It is beneficial as a nasal douche in rhinitis, ozena, etc., or for arresting epistaxis; as a swab for the throat in diphtheria and tonsillitis, and as a mouth wash in oral sepsis, stomatitis, pyorrhea alveolaris, etc.

"P., D. & Co." HYDROGEN PER-OXIDE SOLUTION, when applied to ulcers, softens and dislodges pus, leaving a clean surface for the action of healing agents.

Gauze packing may be removed from wounds with much less pain and bleeding than could otherwise be possible if it is moistened layer by layer with the solution; and plaster of Paris dressings, strapping, etc., may be more readily loosened if treated in the same manner.

In dentistry it may be used to cleanse cavities before filling and to flush tooth sockets after extracting, thereby diminishing bleeding and risk of septic effects.

### "P., D. & Co." HYDROGEN PEROXIDE SOLUTION IS THE KIND THAT KEEPS.

For warm climates it is a necessity. It does not burst the bottles. It is supplied in bottles of 4, 8 and 16 fluid ounces.

When ordering please specify "P., D. & Co."

# Dr. J. Collis Browne's CHLORODYNE

THE ORIGINAL AND ONLY GENUINE.

From Symes & Co., Chemists, Medical Hall, Simla, January 5th, 1880-To J. T. Davenport, Esq., London,

Dear Sir,—Have the goodness to furnish us with your best quotations for Dr. J. Collis Browne's Chlorodyne. We embrace this opportunity of congratulating you upon the widespread reputation this justly esteemed medicine has earned for itself, not only in Hindostan, but all over the East. The other brands are now relegated to the native bazaars, and judging from their sale, we fancy their sojourn there will be but evanescent. We could multiply instances ad infinitum of the extraordinary efficacy of Dr. Collis Browne's Chlorodyne in Diarrhoea and Dysentery, Spasms, Cramps, Neuralgia, the Vomiting of Pregnancy, and as a general sedative, that have occurred under our personal observation during many years. In Choleraic Diarrhoea, and even in the more terrible forms of Cholera itself, we have witnessed its surprisingly controlling power. We have never used any other form of this medicine than Collis Browne's from a firm conviction that it is decidedly the best, and also from a sense of duty we owe to the profession and the public, as we are of opinion that the substitution of any other than Collis Browne's is a deliberate breach of faith on the part of the chemist to prescriber and patient alike.

We are, Sir, faithfully yours,

SYMES & CO.,

WHEN PRESCRIBING CHLORODYNE, REMEMBER TO ADD THE NAME OF "DR. J. COLLIS BROWNE," OTHERWISE A SUBSTITUTE MAY BE USED, TO THE DETRIMENT OF THE PATIENT.

## THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX."

Vol. CXXXVIII.

WEDNESDAY, MARCH 10, 1909.

No. 10.

#### Notes and Comments.

Further Explanation Wanted.

In our correspondence columns we publish a letter from Dr. Charles Hayward, of Liverpool, with reference to our leading article of last week upon "Private Patients in Charitable

Hospitals." On the strength of a newspaper report we stated that "the chairman read from a circular sent to every applicant for attendance in the private ward." The opinion we gathered, presumably as anyone else attending the annual meeting or reading the newspaper report would have done, was that a check was kept on the class of patients concerned by a system of printed circulars. Dr. Hayward now writes that he has publicly challenged the chairman to state whether these regulations were not passed at the committee meeting immediately preceding the annual meeting, and he asks pointedly whether any such form of questions as that read out existed a month prior to the annual meeting. The answer conveyed through the secretary-superintendent, according to Dr. Hayward, while denying the implications, admitted they had been adopted by the committee five weeks before the annual meeting. If the state of things thus described be true, the practice referred to is hardly of the absolutely candid nature that we are entitled to expect in the handling of the affairs of a great Liverpool hospital. There may, of course, be an adequate explanation of the other side of the question. If so, it is to be hoped that the chairman will come forward in person to explain the exact facts connected with the circular letter read by him at the meeting.

It is sad to read in the Annual Report of the Medical Graduates' The Club and Polyclinic that that excel-Polyclinic. lent institution is in a bad way financially. Indeed, if it were not for the generosity of Sir Jonathan Hutchinson, it would have had to close its doors at the end of last year. Everybody knows that post-graduate teaching, so necessary and, until lately, so much neglected, owes more to Sir Jonathan than to any other man living, and it is hard that, after all the years of building up, the institution which he has created and brought to such a high pitch of efficiency should still be so far from self-supporting. It seems that not only had Sir Jonathan to forego the It seems interest on the College mortgage, which he had himself supplied—a matter of £224 a year—but also to find a £100 to prevent there being a deficiency on the year's working. On the other hand, the future seems to be a little brighter, as many mem-bers have increased their subscriptions, and remunerative work in the shape of analyses and reports is growing. For our own part, we can only

say that we should regard it as little less than a calamity if this unique institution were to perish from inanition, and we think it would be greatly to the discredit of the profession if it allowed things to come to such a pass.

Most " Peculiar." THE Peculiar People will have to look to their laurels, for there is a gentleman at Southend who seems likely to out-Herod Herod. Indeed,

he is so "peculiar" that he can find nobody to form a sect with him, and so he remains outside the camp of all religious denominations, but he resembles the Peculiar People, not only believing the Bible literally from cover to cover, but in practising the ordinance recommended by St. James in case of sickness. As he is the only member of the sect, it is obvious he cannot call in an elder to anoint his family when sick, but he remains a convinced faith-healer all the same. Last week he was before the Southend justices on a charge of neglecting to provide medical attendance for his daughter. The unfortunate child had dislocated her elbow, and beyond offering up prayers for her restoration, Mr. Olliver did nothing. The magistrates happily took a more practical view of the situation, fining the parent and ordering the child to hospital. This fanatic bases his trust in supernatural healing, on the fact that he suffered for many years from hernia, and after carefully studying the Bible the hernia disappeared, and he was able to change a bath-chair for a bicycle. We congratulate the Southend Bench on not allowing the painful experiment on his child to be unduly prolonged.

Salvation by Starvation.

In the days when fasting-men were the order of the day at the Aquarium and elsewhere, much controversy took place as to the physiological effects of that process on the organism, but there was a pretty general belief that

most of the "fasts" were such only for business purposes. At any rate, the subjects survived a series of forty days abstinence from food with remarkably little ill effect. In Berlin at present it is said that a Miss Clair de Serval, reputed to be the niece of "Dr." Tanner is submitting herself to a series of fasting experiments at the Charity Hospital. This young lady does not aim at the celebrity conferred by forty days starvation, but is content with ten and twenty days at a stretch. She lives in a glass cage into which air is pumped, and she communicates with a gluttonous world through the prosaic telephone. Miss de Serval asserts that her habits of abnegation have turned her from a neurotic into a healthy being, and that when her

fasts are over she feels like the eagle endowed with renewed youth. We cannot take any responsibility for the genuineness of the experiments, but if the facts as related are even approximately true, the researches of Chittenden and those of the "purinfree" enthusiasts will have to take a back seat in the future. أيذار

It must have been a considerable blow to America when M. and Thor-Rad-X. Madame Curie announced their discovery of radium, for, admittedly, this element has been the wonder of

the world, and not to have been the means of introducing anything big, or showy, or important, must be a very sad reflection to our ingenious and boastful fellow Anglo-Saxons. A little late in the day, but still sufficiently early to be of service to his generation, a Dr. Bailey, of Chicago, has discovered a substance like radium, but, needless to say, much cheaper, less harmful, and of infinitely greater utility. We have not yet heard particulars of the source of this new scientific marvel, but no doubt the anxiety of a wondering world will soon be satisfied by the inventor. At present this astonishing substance revels in the euphonious name of "Thor-Rad-X," and one of its first little feats has been to take a photograph through six inches of wood. After this we are not surprised to learn that among a few of the odd diseases which it will cure almost at sight are cancer, pleurisy, and locomotor ataxy. As "Thor-Rad-X" is said to be cheap, there is an excellent opportunity for some philanthropist to import a ton or two while Free Trade still exists to this country, and start an institute, which will not only relieve the congestion of our hospitals, but bring the healing rays from the dark places of Chicago into the suffering bodies of His Majesty's benighted subjects.

#### LEADING ARTICLES.

THE CHARITY OF THE PROFESSION .-- I. WE lately took the opportunity of quoting from the Sheffield Daily Telegraph some very commonsense remarks on the criticisms passed on medical men for not obeying instanter the calls of midwives to maternity cases. Unlike most journals, our contemporary took the reasonable view that a medical man does not go into practice in a poor neighbourhood for the fun of the thing, but in order to make a living for himself and family. As Mr. Bernard Shaw has lately told us, a medical man is a tradesman who sells advice, and naturally expects that advice to be paid for, as the butcher does his joints or the baker his loaves. Without committing ourselves entirely to that view-which is a little cynical, like most things Mr. Bernard Shaw saysit is obvious that the medical man is as much entitled to see a reasonable prospect of payment for his services before he accords them as is any other worker. In bankruptcy cases the presiding officer not infrequently tells creditors that they are deserving of little sympathy for trusting a man of whose financial position they know little; and yet the medical man is supposed by the public to trust people from whom he knows almost certainly he will never get payment. A medical practitioner in Sheffield has handed to the Telegraph an abstract of his bad debts for five years, certified by a chartered accountant in the city. From this it appears that this gentleman has in that period attended 1,191 persons, whose total fees at ordinary rates amount to no less than £1,260 15s. 11d.—not one penny of which will he ever see! Some of the bills included are for is, and is, 6d.; the highest is only £14. Moreover, in the bulk of these cases medicine was supplied, together, of course, with bottles, corks, pill-boxes, etc., etc. To say nothing of shoe-leather, carriage-hire, and wear and tear, the actual out-of-pocket expenses amount to no inconsiderable sum, and when to that is added the debt for the time and skill expended, we may reckon the £1,260 as the very minimum which the doctor has suffered. This gentleman, then, is dispensing charity at the rate of £250 a year, not, be it marked, on those people and for those ends which he would wish, but probably on a number of worthless creatures who regard him with deadly enmity because they have not paid him. Is this an exceptional case? We venture to hope that it is, that is to say, that the proportion of bad debts here disclosed is somewhat higher than the normal, but we do not think, from what we know of practices in poor neighbourhoods, that it is much out of the way. The gentleman in question does not give his total income, so that it is not possible to say what proportion the bad debts bear to the whole. But suppose we place his earnings at the handsome figure of £1,000 a year, he will be found to be giving away one-fifth to charity, besides any donations that he may give away of his own free will. It used to be reckoned by Mr. Gladstone that a man should set aside a tenth of his income for charity, and we fancy most people would agree that this was a generous proportion. But here we have a gentleman who nolens volens has to part with twice that sum. Will these hard figures strike the imagination of the hard-headed Yorkshireman as representing a little of the benefits which their community derive from the hard work and generous instincts of the medical profession, and will they be inclined, we wonder, to do something for those toil-worn doctors and impecunious widows who, after a life of harassing care, find themselves in their old age dependent on the painfully inadequate charitable contributions of medical men? We wish we could flatter ourselves that they would, but it is a notorious fact that the benevolent agencies of the profession never receive a farthing from the general public. It is universally assumed that because medical men live in decentlooking houses and keep up an appearance of bien-être, that there is always something behind it. How little true this is a search through a few bank ledgers would soon demonstrate. The medical man, theoretically, has to put all his goods in the shopwindow and keep them there. It is his only chance of attracting a clientèle who will pay their bills. It is easy, of course, to write, as we are doing, in a professional journal, but, after all, we are only, so to speak, preaching to the converted. If papers of the power and influence of the Sheffield Daily Telegraph could see their way to keeping this matter of the charity of the profession, ill-requited as it is, in the public eye, a great deal of substantial benefit might accrue, not in the way of making people more honest, but of making them more appreciative of what is done for mankind by medical men who can ill afford it, and—who knows? perhaps even the benevolent agencies of the profession might receive substantial donations.

## THE ADMINISTRATIVE MEASURES AGAINST TUBERCULOSIS.

A SHORT but important paper has been recently issued by the Medical Officer of the Local Government Board. It consists of a memorandum of thirteen pages, in which Dr. Newsholme supplements the circular letter sent by the Board with the Public Health (Tuberculosis) 1908 Regulations to all Sanitary Authorities and Boards of Guardians. Its general scope is set forth in the preamble thus: - "The prevention of tuberculosis and the aid which can be given to patients suffering from it depends in large measure on knowledge of its pathology," and the earlier part of this memorandum deals briefly with this aspect of the Afterwards are set forth the chief adquestion. ministrative measures that can be taken against the disease, and the different forms of aid that can be given to the patient, either through administrative or voluntary agencies. The memorandum extends the campaign against tuberculosis beyond the limits of the Poor-law, so as to include a great mass of poor patients other than those in receipt of relief within the remedial measures rendered available by the co-operation of local authorities and voluntary charities. Another point that should be borne in mind is that the memorandum deals with human inspection alone, with the somewhat dog-matic explanation that "this is chiefly responsible for the causation of pulmonary tuberculosis." The body of the document under notice is devoted to a consideration of the measures which may be utilised against tuberculosis. These may be said broadly to depend on the facts, first, that the disease is caused by a specific pathogenic micro-organism, and, secondly, that it is preventable by hygienic measures that, to be successful, must be administered both collectively by State and other administrative organisations, and individually by the enlightened citizen. In point of fact, the matter stands very much now as it did in the earlier days that followed the famous discovery of Koch; the education of the public and of the individual is absolutely essential. This view is well put by Dr. Newsholme in the proposition that tuberculosis is much more a disease of ignorance than one of misery, as it has often been described, and that many of the measures for its treatment and relief. if properly employed, have amongst their most valuable results the hygienic training of the patient. He enlarges upon the importance of teaching hygiene in school life, and remarks that much more could be done in this direction by special instruction of various social groups, trade unions, friendly societies, and so on, as well as in the Army and Navy. Needless to add, instruction of the tuberculous patient and of his friends is absolutely essential for the prevention of tuberculosis. This can be attained by health visitors, and by disinfection and other special measures devised by local authorities. Any efficient public system, however, must have some machinery of notification and some means whereby early diagnosis is rendered

possible on the part of medical practitioners. So far as the voluntary medical charities are concerned, their most important rôle, after all said and done, is probably educational. Their best curative work is effected by placing the patient under an advantageous environment rather than by drugs. In this respect a great deal may be said in favour of the tuberculosis dispensary, where special attention is given to the early diagnosis of disease. The payment of a notification fee to the medical attendant is properly advocated. As regards the, sanatorium, its value is emphasised in the early and the terminal stages of the malady. In the former it is useful mainly as an educative experience to the patient, and in the latter as removing from a private household an active centre of infection to a specially-regulated environment in which the primary preventive measures of disinfection and isolation are imposed. The whole problem. must necessarily be treated in accordance with local needs and local possibilities. "The best work," says the memorandum, "will be secured if there is active co-operation between voluntary and official workers and agencies, and this remark applies particularly in securing sanatorium treatment for patients." If all the measures within the range of practical action are adopted, there is no reason to doubt that by wise administrative effort following upon the Board's Regulations as to Tuberculosis, the decline in the number of centres of infection can be made more rapid, and thus can be secured a quicker decline in the death-rate from tuberoulosis than has hitherto been experienced. Although, owing to the long duration and occasionally the long latency of this desease, results in regard to it cannot be measured with accuracy except after the lapse of a considerable number of years, it may confidently be expected that administrative measures will enable sanitary authorities gradually to bring tuberculosis within their control, and to secure that it shall become as much a disease of the past in this country as leprosy has become." In conclusion, the attention of readers who are interested in the important question may be specially directed to this official memorandum, which may be purchased for a few pence from the official printers.

#### CURRENT TOPICS.

#### Overcrowding in the Profession.

In spite of the many complaints as to the difficulty of making a fair livelihood in the medical profession, the number of medical men in the Kingdom increases year by year, and the number of entries to the medical schools also increases. It has been calculated that the average income of the medical practitioner is somewhat between £200 and £300 a year, and this is certainly a poor return for an education costing probably £1,000. Moreover, many sources of income are gradually disappearing with the diminishing prevalence of the infective fevers. It is true that new careers for medical men are appearing in these days, such as those of medical officers of health, school inspectors, and so on, but most posts of the sort are poorly paid, and do not tend to raise the average income to any appreciable extent. Under these circumstances, it has seemed wise to many medical men in authority to warn lads who are about to choose their profession against entertaining too rosy views of a medical career. The Manchester and Salford Divisions of the British Medical Association have gone a step further, and have addressed a letter to the headmasters of all the public schools and grammar schools in Lancashire, directing their attention to the conditions we have mentioned, and asking them to make the facts known to boys who think of entering the profession.

#### A Tidal Wave of Influenza.

FOR years past influenza, that most evasive but relentless of epidemics, has ebbed and flowed in monotonous fashion. During the present year, however, it has suddenly swept the United Kingdom with the disastrous force and suddenness of a great tidal wave. Probably at no previous time of its history has this pest been more universal and more disastrous. Last week a large number of deaths were attributed directly to influenza, which has invaded all ranks of society with the wellknown impartiality which characterises this malady. One well-known authority on mental diseases has drawn attention to a fact that has long been recognised in conncetion with influenza, namely, its tendency to lead to melancholia and insanity. It is well that the public should be informed upon this point, so that due allowance may be made for any eccentricities of temper or of conduct on the part of patients, and a careful watch kept upon their If persons who get "bad colds" could only be induced to lie in bed and keep quiet for a few days there would be practically little or no risk of influenza becoming complicated with heart failure and lung inflammations, and the nerve affections that now constitute its chief dangers. But will mankind ever be wise enough in the mass to go to bed and send for the doctor for its minor ailments? Imagination fails to estimate the number of generations of school-board education it will require to evolve such an acme of national wisdom. About that period, also, the disappearance of the last quack nostrum may be anticipated.

#### The Meaning of the word "Sanious."

It is curious to note what entirely different meanings are given to the word "sanious" by different writers. So much is this the case that the true meaning of the word is rapidly being lost. attention has been drawn to this on numerous occasions, and on each of these the user of the word was as confident that he had used it in its correct sense as he was of his use of any other ordinary term. A typical instance of the perverted use of the term is to be found in the current issue of a contemporary, where a writer refers to the fact that, whereas one author is "sceptical as to the existence of real tears of blood," another admits that "in certain circumstances the lachrymal gland secretes a sanious fluid." Here it is obvious that the word is used as a synonym for "sanguineous," and as most medical men are inclined to use it in this sense, it is worth while trying to find its correct meaning. The word is derived from sanies, which is described in the dictionary as being "akin" to sanguis, but which was used by Propertius to signify "diseased or corrupted blood," "bloody matter," and metaphorically in Virgil and Horace of the "slaver" of a serpent. From this word is derived the French sanie, which means "matière purulente, qui sort des ulcères et des plaies non From it also comes the word under soignées." discussion, "sanious," which is defined in Johnson's dictionary as meaning "running a thin serous matter, not a well-digested pus." This definition is practically identical with that given in the present-day medical dictionaries, namely, "of the nature of a fœtid ichorous discharge, containing serum, pus and blood." In spite of the universality of this definition, nine out of every ten medical men will, if asked, say that sanious means bloody, and will use it in exactly the same manner as the writer we referred to above.

Pay Wards in General Hospitals.

A discussion has arisen, somewhat acrimonious in tone, in the Liverpool press, as to the question of the admission of paying patients to general hospitals, and their relation to the visiting staff. It appears that it is the custom of the Royal Southern Hospital to admit paying patients to certain wards at a charge of two guineas a week, the surgeon or physician in attendance giving his services for nothing. It is alleged by those who object to this system that persons are admitted to these wards who are not only able, but willing to pay surgical or medical fees. If this be so-and it would be difficult to think the contrary-then two evils are inflicted by the charities in question. In the first place, the charity robs the general medical men of the city of their legitimate opportunity of earning fees, and, in the second, it does so at the expense of its own honorary staff. We believe that in a city such as Liverpool there can hardly be much real need for pay wards in general hospitals, but if there be, then the medical staff should be allowed to take fees for the work done.

## Home Nursing of Pulmonary Tuberculosis in Dublin.

ONE of the most beneficent activities undertaken as yet by the Women's National Health Association of Ireland is that of the home nursing of persons suffering from pulmonary tuberculosis. Some twelve months ago a scheme was inaugurated by which patients attending the out-patient departments of the Dublin hospitals, who were suffering from phthisis, could, if they chose, ask for and obtain the services of a nurse in their own homes. Two specially-trained Queen's nurses were employed by the Association, and the report of their first year's work has just been issued. It is evident that the nurses have not been idle, and also that their services have been appreciated by the poor. In all, during the year, 7,087 visits were paid, and the work of the nurses kept increasing. In addition to giving the requisite nursing attendance, the visitors gave hygienic advice to the patients and their friends, and were instrumental in many cases in having patients sent to hospitals and sanatoria, or to the country. In addition, they distributed sputum flasks, disinfected rooms, distributed food, paid rent, and found homes for orphan children or for children whose mothers were in hospital.

In fact, they seemed to have acted like the good Samaritan in every way possible. We heartily congratulate the Women's National Health Association on the record of work done. We do so with all the more pleasure in that, while the co-operation and active help of the physicians of the Dublin hospitals was given, their services were not unduly exploited, as has been done in some of the other activities of the Association.

#### The Metropolitan Asylums Board Finance

THE fact that an immense amount of good work has been achieved by the Metropolitan Asylums Board must be generally admitted. The warmest admirers of that body, however, could hardly venture to contradict the fact that the expenditure of the Board is often on a lavish scale. The recent annual statement on its finances dealt with large figures, and it is comforting to note that the outgoings showed a reduction of £133,000 on the average of five previous years. The total gross expenditure was £1,116,000. The cheerfulness of ratepayers will hardly be raised to an exuberant pitch by the state of affairs at the Joyce Green Hospital for small-pox, to which Mr. Spender very properly drew attention. It seems that the institution in question costs £20,000 annually to maintain, and during the past two years it has received only one patient. The total sum of £40,000 has therefore been drawn from the pockets of the ratepayers, in order to tend a single person suffering from small-pox. The superintendent, it was stated, draws £700 a year. That there should be small-pox accommodation available in the metropolis is evident, but that it should be provided and maintained at this rate of wanton extravagance is explicable only upon the ground that the Metropolitan Asylums Board, not being a directly elected body, can afford to disregard the monetary interests of the ratepayers. It is to be hoped that the Local Government Board or some central controlling authority will induce the Asylums Board to devise some scheme whereby the wards of Jovce Green Hospital may at once be put to some useful purpose, instead of lying vacant for the epidemic of small-pox that may possibly never again invade London.

#### PERSONAL.

It is announced that Surgeon-General George Bourke, C.B., has been appointed Hon. Physician to the King, in succession to the late Surgeon-General T. Tarrant, C.B.

DIRECTOR-GENERAL SIR ALFRED KEOGH, K.C.B., is to be made the recipient of the Honorary Degree of LL.D. at Edinburgh University.

LORD ASHBOURNE will be the guest of the evening at the Annual Dinner of the Irish Medical Schools' and Graduates' Association, to be held at the Hotel Cecil on March 18th.

THE LORD MAYOR has promised to take the chair at the 81st Annual Meeting of the Royal Free Hospital, to be held at the Mansion House this afternoon, when a special appeal will be made for funds. Dr. Prosper Liston received a handsome testimonial on leaving Penryn, he having accepted a Government appointment at Penang, in the Straits Settlements.

SIR VICTOR HORSLEY has been appointed Linacre Lecturer at St. John's College, Cambridge. His lecture, to be delivered on May 6th, will have as its subject, "The Motor Area of the Brain."

DR. C. R. CLARK, Physician to the Toronto Hospital for the Insane, has been appointed Dean of the Medical Faculty of the University of Toronto in succession to R. A. Reeve, whose name is well-known in this country.

AT a recent meeting of the General Court of Governors of Guy's Hospital, the vacancy on the Obstetric staff of the hospital, caused by the resignation, a few weeks since, of the late Dr. Peter Horrocks, was filled by the appointment thereto of Mr. Guy Bellingham Smith, M.B., F.R.C.S.

THE Council of the University of Liverpool, at their last meeting agreed to establish a Profesorship of Forensic Medicine in the University, and appointed to the Chair Dr. R. J. M. Buchanan, who has held a lectureship in the subject in the University for the last three years. Professor Buchanan is a recognised authority on his subject, as is shown by his published work.

THE Gold Medal founded by the late Sir Gilbert Blane, Bart., to be given biennially, has been awarded by the Medical Director-General of the Navy and the Presidents of the Royal Colleges of Physicians and of Surgeons to Staff-Surgeon Charles R. Nicholson, for his Journal of H.M.S. Egmont, November 6th, 1906—December 31st, 1907, and to Staff-Surgeon Arthur W. B. Livesay, M.B., for his Journal of H.M.S. Bonaventure, April 2nd—December 31st, 1907.

Professor Galt, Dean of the Medical Faculty of St. Mungo's College, Glasgow, has been appointed to the post of Pathologist to the Stephen Ralli Memorial Laboratory at the Sussex County Hospital, Brighton. During the eleven years since his appointment to St. Mungo's College, Professor Galt has done good service, and as a teacher he has been greatly appreciated by many students, perhaps more especially by those who took their post-graduate studies in Public Health work under him.

At Southport on March 1st the Mayor presented to Dr. John Hargreaves Robinson a gold watch, awarded by the German Emperor in recognition of his services in helping to rescue the crew of the German steamship Nord See, of Lubeck, which was sunk between Hull and Hamburg last May by collision with the Avoca.

The watch is emblazoned with the German Imperial crown, and bears the Kaiser's initial, and it was accompanied by a letter of thanks from the German Government. For helping in the work of rescue and afterwards professionally attending those of the crew of the Nord See who had been submerged Dr. Robinson also received the Hamburgische ferein Seefahrt medal. Dr. Robinson last week was appointed Surgeon of the Western Telegraph Company's cableship Norseman, at present stationed on the East Coast of South America.

#### A CLINICAL LECTURE

ON

#### THE PRESENT POSITION OF INTRAVENOUS TREATMENT.

By FELIX MENDEL, M.D.,

Essen (Ruhr).

[SPECIALLY REPORTED FOR THIS JOURNAL.]

PART II.

A NEW and very promising era for treatment by intravenous injection by atoxyl has quite lately been opened up in the employment of the method in the treatment of protozoal diseases, trypanosomiasis,

syphilis and malaria.

If, in spite of the great services of Koch in combating sleeping sickness by means of the subcutaneous injection of atoxyl, the success desired has not been attained, the cause has been that, notwithstanding the enormous dose, it has not been possible to establish the necessary concentration of the remedy in the blood fluids that seem to be required to kill off the protozoa at a stroke, and so in "one act to effect a sterilisation of the infected organism" such as Ehrlich desired to accomplish. Insufficient repeated doses, instead of destroying them, make them firm against the atoxyl (atoxylfest), and in this way the only known specific remedy is perfectly inert.

Even if a high dose bordering on intoxication were used by subcutaneous injection, sterilisation would still not be attained, as with the slow absorption of the remedy from the connective tissues, and its gradual passage into the blood channels in small quantities, the excretion from the kidneys would keep equal pace with it; with intravenous injection the arsenic reaches the blood current in full dose and in the highest degree of concentration, and leaves them rather more slowly than medicines that reach them by way of absorption in divided doses. Therefore, if possible at all, the intravenous injection of arsenic is alone in a position to effect "sterilisation in one act" required by Ehrlich, and to bring about the definite cure of sleeping sickness.

With the treatment of syphilis and parasyphilis by large doses of atoxyl, as Salmon and many German authors recommend, I have met with nothing but failures, indifferently whether the atoxyl were given subcutaneously or into the veins. On the other hand,

failures, indifferently whether the atoxyl were given subcutaneously or into the veins. On the other hand, the administration of small doses gradually increased—0.05 to 0.15—has shown in these diseases also that atoxyl, especially when used in the thoroughly effective and yet sparing manner into the vein, that it belongs to that class of highly important remedies that have

to that class of highly important remedies that have a favourable influence on the nutritive processes, and heighten the resisting power of the organism.

By means of intravenous injections of quinine, Baccelli has been able to save serious cases of malaria, cases apparently doomed to death. Atoxyl has proved its value in this form of protozoal disease when injected subcutaneously. Why should not atoxyl, just as well and perhaps better than quinine, have its curative action against malaria heightened when given by way of intravenous injection? The correctness of this assumption I can prove, it is true, only by one grave case of malaria that had been refractory to quinine, and only recovered after injection of 1.5 grm. of atoxyl given in 5 individual doses. Wider experiences must show whether, in intravenous treatment by atoxyl, we have a further remedy against malaria equal to quinine, and perhaps in many cases superior to it.

(4) Intravenous Treatment by Salicylates (F. Mendel). In order to avoid the disagreeable by-effects of the salicylates on the intestinal tract, and which rarely fail to be present, and at the same time attain the highest effect with the smallest possible dose, the intravenous injection of small doses of salicylate of soda was recommended by me, and especially as the subcutaneous employment of it was out of the question owing to the great pain it caused.

The most active and the most suitable for use was a 20 per cent. solution of sodium salicylate, the injection of which, with the addition of caffein, is perfectly painless and free from irritating effects:

R Natrii salicylici, 8.o.
 Caffeini natrii salicylici, 20.o.
 Aq. destillatæ, ad. 5o.

Or,

Natrii salicylici, 8.75. Caffeini, 1.25. Aq. destillatæ, ad. 50.

These solutions, at first clear as water, become coloured when exposed to light and air; they become reddish-grey or brown, and their reaction also changes, and these are changes that are not absolutely irrelevant as far as intravenous injection is concerned. For an injection fluid so changed may set up thromboses and cause rigors, whilst these disagreeable byeffects are excluded with some degree of certainty by the use of unchanged solutions. For this reason an advance not to be undervalued as regards intravenous therapeutics is the introduction of a solution prepared according to my directions in ampullæ by the Vereinigten chemischen Werke in Charlottenburg, under the name of attritin, and furnished at a reasonable price.

Intravenous treatment by attritin injected once or twice a day according to requirements, has, from our experience, but little vasomotor, and with it antifebrile, action, whilst its antitoxic effect on the pain and swelling of the joints must be called quite remarkable. In febrile rheumatic affections we must bring the internal use of the salicylates into the field first, and if from any cause this fails, we can replace it by intravenous injection, which then from its great antitoxic action is often followed by brilliant results. For the reasons stated, the afebrile rheumatic affections will always be the special domain for the employment of attritin by intravenous injection, and here this method of using the salicylates will, in spite of the small dose, from the high degree of concentration of the drug on its entrance into the blood current and its slow elimination, often bring about positively striking symptomatic and even curative results.

Troupel, who has collected the results of an extensive employment of the salicylates, has made use of it by the vein and with success in chronic articular rheumatism, whether chronic deforming arthritis on arthritis ankylopoietica following acute rheumatism. It is in just these incurable forms that "salicylic treatment, especially in the form of intravenous injection of F. Mendel, Essen, has done the best service in combating the pains often so crippling and hard to bear."

(5) The Intravenous Employment of Digitalis (Kottmann, Mendel, Fraenkel).

The possibility of introducing digitalis substances directly into the blood current without local or general mischief is very important for those cases in which threatening conditions demand speedy interference, or in which internal treatment seems to have lost its effect, or, from whatever cause, no effect has been produced. Intravenous treatment is of special value in such cases, as it puts us in a position of being able to avoid those rocks on to which digitalis treatment, however carefully carried out, not unfrequently casts us. It allows the possibility of accurate dosage—i.e., the precise determination of the quantity of the medicine entering the blood current and there coming into action, which in the case of internal or subcutaneous

administration depends, and especially in pathological conditions, on very varying and incalculable conditions as to absorption from the stomach and subcutaneous connective tissue. It further avoids also the disturb-ing symptoms of irritation that all preparations of digitalis hitherto known, and however they are employed, set up at the site of application. Finally, by proper selection of the preparation to be employed, it permits us to avoid the toxic cumulative effect, and with it the last rock of digitalis treatment, as the intravenous treatment works with separate strokes, the effect of which we can observe and follow before sending a second dose after it. As digalen, that was first introduced into therapeutics by Naunyn, proved to be unsuitable for subcutaneous injection, on account of the irritation it caused, and as it also acted no more speedily than when introduced by the mouth, Kottmann, in order to get a quicker effect, ventured to inject it direct into the blood current, although pharmacologists up to the present are not agreed as to its chemical composition. Kottmann at first was not afraid to give doses even from the first of 5 to 10, and even 15 ccm.; but, bearing in mind an experience gained in the klinik at Berne, in which foudroyant cardiac death took place immediately after an intra-venous injection of o.6 strophanthin, he was more cautious in regard to dosage, and particularly in regard to digalen, and in a work published by him on the subject he recommends 1 ccm. as the initial dose, and only to proceed to larger doses when this fails to produce the desired effect, which, however, may be suitably replaced by small doses more frequently repeated.

It must appear striking that such large doses can be borne at all without doing any mischief when injected into the veins, especially when we assume, with Cloetta, that digalen is really pure, soluble digitoxin. Neither Kottmann nor Cloetta have been able to explain the non-poisonous nature of a substance otherwise so poisonous as digitoxin, and when employed in such

an energetic manner.

Digitalone, recommended by me for intravenous medication, is a preparation made from fresh digitalis leaves of a concentration of 1 in 10, and contains the most active principles of the drug digitoxin in a condition analogous to that of digalen, in which, according to the investigations of Cloetta only, it exercises a cumulative action when used in very large doses. For therapeutical purposes such doses, however, are not required in the case of digitalone, as it is not a single substance, but comprises all the active glycosides of the digitalis leaves, the combined action of which is necessary for an effect to be produced. As, how-ever, according to known pharmacological laws, the collective action of these substances is greater than the sum of their individual actions, in order to produce a sufficient effect digitalone requires such small doses that the unexpected conversion of increased cardiac activity into a toxic one, with diminished action of the heart, is excluded.

The intravenous infusion of this preparation of digitalis showed itself to be perfectly harmless. It neither causes irritation at the point of injection, nor any general or local disturbances whatever. On the other hand, signs of pronounced digitalis action appear within a short time of the injection, marked by more powerful systole, lengthened diastole, and increased

blood pressure.

This therapeutical effect of the single dose, which naturally can only lead to a permanent effect by a number of doses, sometimes comes on within a few minutes, sometimes later, and is more or less marked, according to the nature of the illness. But it is well to bear in mind that it reaches the height of its action generally after a few minutes, and its action ceases very gradually in from 24 to 30 hours. This affords sufficient indication of the time for repeating the dose, which for the adult is 2 ccm., but, with delicate individuals, the dose must be correspondingly less. If a therapeutical accumulative action is required, the injections must be repeated every 12 or 24 hours, and before the effects of the previous dose have passed off, whilst with relative insufficiency and so-called chronic digitalis treatment longer intervals are allowed (two to three days). In threatening conditions, where any effect at all could be expected, a single dose has proved sufficient to obviate the danger to life and relieve the distressing symptoms in a very short time. The almost absolute absence of danger of accumulation also allows us to send in whatever further injections are

required without anxiety

It must be conceded that in quickness and power these two cardiac remedies are exceeded by strophanthin-Boehringer, first recommended by Fraenkel. The action of strophanthin, which is injected in doses of mg., but which should not be given in frequent doses on account of the great danger of accumulation, acts, according to Fraenkel, like a charm, and commences within the first three or four minutes, the change of the pathological condition to the normal takes place before our eyes. The patient's pulse becomes fuller, his respirations are less frequent, and a flood of urine sets in such as we have never seen by any other means in such a short time. One patient who before the commencement of the treatment lav in a condition of apathy, with all the symptoms of over-loading with CO<sub>2</sub>, revived rapidly; another, who showed the appearances of excessive cardiac dyspnœa, and the restlessness and anxiety caused by it, became calm, and many, even after the first injection, regained the sleep that they had been deprived of for weeks.

In this remarkable action of a single dose of strophanthin, however, there lies a danger that must not be under-estimated. The diseased heart is called upon suddenly and immediately to do extra work; if the reserve power of the heart is equal to the requirements, the therapeutical effect is brilliant. But in other cases, in which the condition of the cardiac musculature is not one in which a response is possible, it will answer to the stimulation with diminished efficiency, and still greater disturbance of function, and in the worst cases even with sudden death.

A number of cases are recorded in which sudden death has taken place after injection of strophanthin. In making use of this remedy by way of intravenous injection, therefore, special care and caution must be used both as regards the indications and the dosage.

As regards the dangers of strophanthin, the

fact is important that the therapeutical dose and the toxic dose are very near each other, to which Liebermeister has lately drawn attention. Further, that it is extraordinarily cumulative, and may cause sudden

cardiac death without warning.

We know from experience that the cardiac remedies now discussed, even when given in the most efficient manner by intravenous injection, often fail like all other stimulants, or have only a transient effect, when the blood pressure sinks as from the absorption of septic material in peritonitis; the heart loses its power, and, with increasing weakness, the gravest circulatory disturbances threaten life. In such cases Heidenhain, after von Romberg and Passler, had determined the powerful action of adrenalin in raising the blood pressure, recommended the intravenous infusion of adrenalin-saline solutions, and in this way obtained an absolutely life-saving effect.

The method consists in the infusion of a litre of physiological saline solution, to which has been added 8 drops of solution of adrenalin. Rothschild, who made use of Heidenhain's treatment in an unusually bad case of peritonitis, describes its action as follows Even within a few minutes of the commencement of the infusion, the pulse improved, and quickly became strong and tense, and showed these qualities for halfan-hour after the completion of the infusion. In like manner the subjective condition improved with surprising quickness, and the ominous feeling of passing away gave place to one of well-being. Naturally, there is nothing to prevent a repetition of this, if necessary, and which may be required on further sinking of the blood pressure.

From this short statement we see the great importance of intravenous therapeutics in the treatment of disturbances of the circulation. The intravenous use of active remedies, when all other methods fail, enables us to give a powerful impulse to the flagging heart, and thereby turn aside the danger that threatens

(6) Various further Remedies for Intravenous Injection.

It was to be expected that, with the gradual further spread of intravenous injection, fresh proposals for the treatment of general infective diseases by that

method would soon be made.

The excellent effect produced by quinine when introduced into the veins in malaria, induced Lenzmann to try it in the second protozoa disease—syphilis, and he felt himself the more justified in this as other medicinal substances, atoxyl, had proved useful in both affections.

From a private communication of Lenzmann's, he now employs the following method in the treatment of syphilis :-

Quinin. lact., 10. Sod. chlorat., o.8. Aq. destill., ad. 100.

He first injects 2 gm. of this solution, and increases the daily dose to 0.5 in women and 0.7 in men. Slight giddiness and rush of blood to the head, as well as noises in the ears, come on with these large doses, but pass away quickly, and particularly as the patient gets accustomed to them. Lenzmann considers quinine to be an excellent remedy in syphilis, not equal to mercury in its action, but in cases in which only small doses of the latter are borne, or when there is any idiosyncrasy as regards the drug capable of doing excellent service.

If the statement of Lenzmann should be confirmed after extensive trial, the quinine treatment of syphilis

would be recognised as of great value.

Doevenspeck has tried 2 ccm. of a 5 per cent. solution of potassic iodide—o.1 gm. of the drug in syphilis, that required a rapid effect, and even from the first doses obtained a wonderful effect in the various stages of the disease, from the primary sore to syphilitic cerebro-spinal disease.

Unfortunately, I was not able to confirm these statements from my own observations. I have tried the treatment in a number of cases similar to those mentioned by Doevenspeck without the slightest trace of success. The nocturnal headaches did not disappear; ulcerations made their appearance, which, Doevenspeck said, were scarcely visible after the second injection, even when of great extent and threatening perforation, even after doses given repeatedly with only a tendency

to healing.

As, moreover, the injection of potassic iodide proved to be almost always painful, I have given up its further use by way of intravenous injection, as has been shown by carefully conducted experiments on animals, that the potassium salts, when introduced into the blood even in small quantities, cause a rapid diminution and final cessation of muscular movement, as well as a rapid cessation of the action of the heart in the animals experimented on, whilst, when given by the mouth or subcutaneous connective tissue, only much larger doses produce a fatal effect. The fatal dose corresponds exactly to the potassium constituent, and is not influenced to any degree by the metal constituent.

We see from these interesting animal experiments how necessary a full knowledge of the pharmacological properties of a medicinal substance is, as regards intravenous injection before it is applied in the way of

Now, according to the same experiments, the sodium salts, when injected into the blood in even many times larger quantities, have no influence on the heart nor any appreciable effect on the central nervous organs, or the muscles or nerves. In place of potassic iodide, therefore, I have used sodium iodide in 20 per cent. solution for injecting into the veins, and have injected 2 ccm. of this mixture, which was borne without either local or general injury.

But in syphilis, which appears to require large doses of iodine, I have never seen any improvement from this treatment; but, on the other hand, I have used intravenous injections of sodium iodide with remarkable success in parenchymatous struma, especially forms of Basedow's disease and arterio-sclerosis, concerning which I shall give a detailed account in another

As the duration of the excretion of sodium iodide depends on the kidneys-although this does not belong to treatment by intravenous injection—the intravenous injection of small doses of the drug, and the accurate control of its excretion, forms the most reliable indica-tion of the integrity of the renal functions when poured directly into the blood channels, the time of its in-corporation and the exact dose can be determined, whilst in the case of administration by the mouth the passage of the dose into the mass of juices, and the point of time of its entrance, depend on the condition of the intestinal tract at the time.

The proof that iodine is being excreted, and the length of time during which the excretion takes place, as shown by Bourget's reaction papers, give us a simple means of testing the function of the kidney, and also that of its eliminating power, one that is, at least, as reliable as testing with methylene blue, phloridzin and other things. In the case of harmless albuminurias, the duration of the excretion is always normal, whilst a considerably lengthened power in that direction, and is a significant with the direction and is a significant with the direction. that direction, and is a signum mali ominis for all cases of renal disease.

The period until complete elimination has taken place varies in healthy individuals, and the individual dose of 0.4 gm. takes between 20 and 30 hours, whilst in cardiac and renal cases a similar dose can often be traced in the urine and saliva for more than 50

or 60 hours.

As two further therapeutic attempts to treat acute infective diseases by way of intravenous injection, I would first mention that of Charles Barrow, who used would first mention that of Charles Barrow, who used a solution of formaline (1 in 5,000) in a case of puerperal septicæmia with a remarkably good result, and, further, the injection of a solution of nitrate of silver (500 ccm. of a 1—10,000), first recommended by Hume and tried by Schatski and Grjasnow. According to these authors, the injection, after a short general restion (favor rigors etc.) has a favourable effect not action (fever, rigors, etc.) has a favourable effect, not only in genaral infections, but also in local ones having marked toxic symptoms.

The most recent of the attempts to treat cases by means of intravenous injection is that of Van der Velden, who injected 3 to 5 ccm. of a 10 per cent. solution of chloride of sodium in a case of hæmoptysis, and obtained a measurable increase of coagulability of the blood in the course of 2 to 4 minutes. By this simple treatment, which probably depends on mobilisation of the thrombokinasis from the tissues, Van der Velden has obtained good results. From this basis it may well be expected that this treatment will prove successful in hæmorrhages from other causes that are difficult to arrest (ulcer of the stomach, intestinal hæmorrhages, etc.)

Finally, I would like to mention a thiosinamine combination (fibrolysine) that has been injected both into the muscles and into the veins in doses of 2 to 3 g. of a 10 per cent solution, when the softening action on cicatricial tissues takes place very quickly, both in my own experience and in that of other authors.

With the above I believe I have given a fairly com-

plete account of the present position of intravenous therapeutics, and have at the same time shown the great practical importance of our method of treatment, which in the most varied forms of disease has shown itself effective when every other method of administering medicines has failed.

We must confess that intravenous therapeutics makes we must comess that intravenous therapeutics makes special demands on the caution, care, and dexterity of the physician, and that a number of difficulties that are not to be under-valued are associated with it; but, in the interest of our patients, we must take them as they come, willingly, when in exchange for them we acquire certainty of dosage, increased efficiency, as well as painlessness in the administration of our remedies. of our remedies.

NOTE .- A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by G. Milian, M.D., Physician to the Peris Hospitals. Subject: "Hemiplegia due to Syphilitic Artoritie.

#### ORIGINAL PAPERS.

#### SURGICAL AID IN CHRONIC ULCER OF THE STOMACH. (a)

By J. A. NIXON, M.B.CANTAB., M.R.C.P.LOND., Physician to the Bristol Royal Infirmary.

A constant succession of dyspeptics, some alcoholic, some phthisical, all full of strange complanings in terms borrowed, for the most part, from soul-stirring newspaper advertisements, passing rapidly through an out-patient clinic, is calculated to blunt one's interest, and to lull one into the passive belief that none are ever cured, and that the majority of them may be relieved by copious irrigation of the stomach with concoctions of rhubarb and gentian. Invaluable as this remedy proves in a great number of cases, it cannot be regarded as a panacea for every variety of digestive disturbance, and of late years its pre-eminence has been challenged by the surgeon. The operative treatment of chronic gastric ulcer has been attended by such noteworthy results that the physician is tempted sometimes not to discriminate too closely, but to submit any and every case of indigestion to operation, with the inevitable penalty of disappointment.

Whether gastro-enterostomy in one of its forms is the best operation that can be devised, or whether some better procedure will presently be introduced, is not the object of discussion in this paper. So far as it goes it is a good operation; it relieves the patient under certain conditions; and the duty of the physician (in the intervals of suggesting fresh plans for operation to the surgeon) is to endeavour by every means in his power to select those cases that are likely to benefit from surgical interference, and learn to know those in which no good results are likely to follow.

The cases under my care which have been operated upon, in the belief that a chronic ulcer of the stomach or duodenum was present, are shown in the following

Ten cases suspected of chronic ulcer do not form a large series from which to arrive at general conclusions, but they provide illustrations of the difficulties en-

ditions which surgery will relieve.

Case 1.—T. C. G., a man, æt. 53. Eleven years previously suffered from vomiting (daily for three weeks), with a single large hamatemesis. Six years ago treated for gastric ulcer, and again one year ago when he vomited frequently, sometimes "coffee grounds." No pain or tenderness, no gastrectasis, some indefinite resistance in epigastrium. Argyll-Robertson pupils, knee-jerks present, no inco-ordination, analgesia in arms and legs. Free HCl absent, and lactic acid (0.129 per cent.) present in gastric juice.

Here there seemed so much room for doubt that, in spite of recognising the fact that the man was probably suffering from spinal sclerosis, operation was advised. It was possible that there was some old ulcer or carcinoma of the stomach, and the general condition of the patient was fair. An exploration was made, no ulcer or growth was found, gastro-enterostomy was performed. Three months later he was well except for slight fulness after meals. Subsequently the vomiting recurred temporarily. The conclusion is that these attacks are gastric crises, yet there was good reason for believing it might be otherwise, and the patient suffered no ill-effects from his operation.

CASE 2.-A. H., a man, æt. 32. Four years ago was warded for a month on account of vomiting blood and diarrhœa, one year ago a similar attack lasting six weeks. A fortnight before admission he had vomiting with blood. Vomiting always occurred soon after food. Painful spot in the nipple line just below left hypochondrium. Extreme emaciation. No signs of other

At the operation no ulcer, growth, or adhesions were found, but gastro-enterostomy was performed. Immediately the man improved and put on flesh (this had not been the case under medical treatment), but he has relapsed several times. Once he developed an ulcer of the larynx, and several times since he has had numerous

(a) "Bristol Medico-Chirurgical Journal," September, 1908.

small superficial ulcers in the mouth, suspected variously of being syphilitic or tuberculous. On the last occasion he came under observation it was evident that these ulcers started as blebs. Perhaps pemphigus is their true origin. Still, the improvement after operation was remarkable, and the patient has never seen reason to regret its performance.

CASE 3.—M. C., a girl, æt. 14, who had persistent vomiting of food with so much epigastric tenderness and pain of paroxysmal character that, although she had a few pleural crepitations at the right base, it was decided to perform an exploratory laparotomy. She urged us to operate, the pain was so severe, and she was so sure of its localisation.

Mr. Carwardine explored, and found an abnormal attachment (? congenital) of the omentum to the anterior abdominal wall; this he divided, but did not open the stomach. There was no external sign of ulcer. Eventually she developed extensive diffuse phthisis, and her pain was in no way relieved Doubtless this pain was connected with a diaphragmatic pleurisy.

CASE 4.-F. C., a girl, æt. 19, with a history of six years' indigestion, constant pain relieved by lying down; vomiting at no definite time after meals; three years ago a single hæmatemesis; slight epigastric tenderness, no gastrectasis. She described her pain as so severe, so localised, and as making her life such a burden, that she begged for an operation "to see if there was not something there." Medical treatment had always failed to do any good.

Mr. Munro Smith operated, and found a stomach firmly adherent on its posterior aspect to a mass feeling the size of a cricket ball, which presented no prospect of safe removal. Gastro-enterostomy was performed. There was complete relief from pain; no recurrence; the girl put on flesh; two and a-half years afterwards could eat "just anything," and was happily married.

CASE 5.—L. D., a girl, æt. 18, with the appearance of a fairly healthy child of 12 (Lorain's infantilism). Epigastric pain, worse after food, for two years. Hæmatemesis (Oj) nine months ago, and one month later. Great cutaneous hyperæsthesia in epigastrium. Enormous gastrectasis, greater curvature just over pubes. Had menstruated once at 13, absent since.

Gastro-enterostomy performed by Mr. Carwardine. Inflammatory tumour found, completely obstructing

pylorus. The relief was immediate, the child grew into a woman in a few weeks. The stomach remained distensible for many months, and at rare intervals there was vomiting. The weight increased in eight months from 6 st. to 10 st. 3 lb. After six months the stomach could no longer be abnormally distended with seidlitz powder. Eighteen months after operation was in excellent health and appeared a healthy young woman of 20; catamenia regular.

CASE 6.—A. H., single woman, æt. 34. Indigestion on and off since childhood. Hæmatemesis three years ago. Pain directly after food, temporarily relieved by medical treatment. No vomiting, no tenderness, no

gastrectasis.

Laparotomy by Mr. Carwardine. Hour-glass stomach, also scarred duodenal ulcer obstructing pylorus. Gastro-jejunostomy and gastro-gastrostomy performed. The relief from operation was considerable, but at times indigestion returns (eighteen months after operation). The patient is very glad she was operated on.
CASE 7.—M. V., matried woman, æt. 37. Fourteen

years ago vomiting after food with streaks of blood; irdigestion on and off ever since. Pain directly after food in epigastrium and back. Water-brash, gastrectasis, lump felt in epigastrium. Gastric juice, free HCl, no lactic or butyric acid.

Gastro-enterostomy by Mr. Carwardine. Duodenal adhesions and considerable dilatation of stomach found (? duodenal ulcer). Marked relief of indigestion

and water-brash, continuing for two years.

Case 8.—C. G., single woman, at. 37. Frequently under treatment for dyspepsia during past sixteen years. Pain about one hour after meals, relieved by vomiting. Hæmatemesis eight years and six years ago. In latter years vomiting less frequent, but the desire to vomit has increased. Superficial cutaneous hyperæsthesia and some deep tenderness in epigastrium. No gastrectasis.

Gastro-enterostomy performed by Dr. J. Swain. Pylorus not apparently thickened, no ulcer found, but very great relief from the operation. The patient is a maid at the Bristol Royal Infirmary, and is under constant observation. Her satisfaction ten months after operation is undiminished. operation is undiminished.

CASE 9.-K. S., married woman, æt. 46. For twelve months had complained of pain just below left hypo-

chondrium one hour after food. Sickness after every meal, which used to relieve the pain, but later ceased to do so. Always free from pain when constipated or when lying down. Never hæmatemesis. Slight tenders in epigastrium, no gastrectasis.

Operation by Mr. Bush. Marked puckering along lesser curvature of stomach, an indurated mass involving equally anterior and posterior surfaces, and reducing the length of lesser curvature to one-half of Gastro-enterostomy performed with complete normal. and lasting relief (one year later).

and lasting relief (one year later).

CASE 10.—J. M., man, æt. 55. For five years pain after food, vomiting (a pailful at a time) for twelve months. Progressive wasting, lemon tint of skin noticed by friends. Gastrectasis, visible peristalsis, lesser curvature just below umbilicus. A firm "knob" felt at right edge of right rectus when peristalsis reached this point. Liver dulness displaced downwards but not enlarged. Gastric juice: free HCl absent.

absent.

Operation by Mr. Hey Groves. Pylorus thick and nodular, anterior surface marked by scar to which omentum adhered; complete pyloric stenosis. Gastroenterostomy performed and piece of tumour removed for examination. Pathological report: At first only inflammatory tissue found, but later in posterior pyloric wall undoubted area of columnar-celled car-cinoma. Twelve days after first operation Mr. Groves performed pylorectomy. The patient made a good recovery and experienced great relief from the operation (after six months).

Analysis of seven cases improved by operation:-

... 7 cases. Pain present in Vomiting present in... Hæmatemesis present in ... 4 cases. ... 3 cases.

Stenosis present in ... ... 3 cases.

In discussing these cases one is tempted to look for some leading symptom or combination of symptoms, or to hope for some mechanical (chemical or otherwise) method of arriving at a diagnosis of chronic ulcer of the stomach. But excepting pain and vomiting, there seems no other reliable sign, and these two are shared

by many other diseases.

Gastric contents.—Little or no help is derived from the test-meal, and the presence or absence of this or that constituent. A considerable experience of "test-meals," carried out in various hospitals upon the subjects of many diseases, carries with it the conviction that "test-meals" offer absolutely no reliable division of gastric means oner absolutely no reliable division or gastric cases into those which will and those which will not benefit by operation. Hyperchlorhydria, hypochlorhydria, achylia gastrica, deficient or increased motility, will none of them give the unfailing indication.

Gastrectasis is by no means necessarily present in the cases which profit most by gastro-enterostomy.

Tumour.—The presence of a palpable tumour means very little in the diagnosis between inflammatory tissue and neoplasm; its absence has no bearing on the question of a profitable or unprofitable operation.

Hamatemesis or Melana.—Both these signs are most

misleading. Hæmatemesis in small quantities as described by the patient is most difficult to distinguish from hæmoptysis. Malignant disease, especially in the early stage, occasionally causes a single large hæma-temesis. Duodenal ulcer is not uncommonly associated with hæmatemesis and melæna from regurgitation of blood through the pylorus. The erosion of the liver by an adherent simple ulcer will give rise to constant "coffee-ground" vomiting.

Hæmatemesis from a general oozing of the gastric mucosa (gastrostaxis) is not unknown, may be very

cutaneous hyperasthesia, especially galvano-hyperasthesia, may be of great help in diagnosis. The absence of this sign need deter no one from operation

if other indications are present.

The chief guide to operation is the patient as a whole. A long history of indigestion, with vomiting and occasional attacks of hæmatemesis dating from early adult life (I begin to think that gastric ulcer is not so very rare in children of 12 or 14) will form the foundation of most accounts of chronic ulcer. While to these may be added epigastric pain—pain before food, directly after food, an hour or two after food, and pain all the time; the sufferers from ulcer of the stomach or duodenum know all these variations. A resistance, thickening, or definite lump in the epi-gastrium only forms an additional reason for operating; and gastrectasis with visible peristalsis as ascertained by inflation with CO<sub>2</sub> clinches the matter.

Operation is indicated in:—

(a) Painful ulcer.

(b) Recurrent hæmorrhage.

(c) Pyloric stenosis.

In these three conditions there will probably be no difference of opinion as to their suitability; but there is one more class, consisting of chronic dyspeptics, who, having honestly tried medical treatment, find themselves unrelieved. With the proviso that operation is not undertaken for the following conditions, they should be operated on:—

(1) Chronic alcoholism or drug-taking.

(2) Gastric crises.

(3) Phthisis.

(a) Dyspepsia. (b) Hæmoptysis.

(c) Diaphragmatic pleurisy.

(4) Mitral stenosis.

(a) Pain.

(b) Hæmoptysis.

(5) Cirrhosis of liver.

(6) Chronic Bright's disease (dyspepsia).

(7) Renal colic.

(8) Addison's disease (nausea, vomiting and faintness).

(9) Overloaded or distended colon.

(10) Arsenic poisoning.

Atonic dilatation.—Clifford Allbutt says that "the frequency of dilatation of the stomach as a complication or sequel of acute disease is not sufficiently appreciated" in the estimate of the causes of dilatation of the stomach not depending on pyloric stenosis, and he quotes (not in agreement) "a London physician of almost singular eminence" who said to him "that of dilatation of the stomach apart from pyloric obstruction he knew nothing." Yet, except during convalescence from an acute disease, I believe the diagnosis of "atonic dilatation" should be received with the utmost scepticism. It has been quite astonishing to find how frequently the post-mortem or (in modern times) the operating table has shown an obstructive cause for the so-called atony. Unless such a case yields very quickly to diet and treatment, it should be explored.

For general neurotic symptoms co-existing with a dilated stomach no great respect is demanded. Constant dyspepsia is as liable to cause as to be caused

by "a general neurotic disposition."

Our army of neurasthenics is an ever-diminishing one, and as a disinterested observer of a very large number of surgical operations, I shall never make the diagnosis of "gastric neurosis" with complete assurance, nor hear it made without a lurking suspicion that some day surgery will "inconveniently confront us" with something more tangible than our own maxims, and a very solid basis for the hypochondriacal disorder.

In a very great measure the patient is his or her own, and our best guide, if, being of sound mind and appreciating fully the risks, such an one comes deliberately to the conclusion that the pain, vomiting, discomfort and emaciation make life no longer worth living. Then, in the absence of other contraindications, we are amply justified in advising, if not gastro-enterostomy, at least an exploratory laparotomy.

One last word on the after-treatment. After a gastro-enterostomy has been performed by any of the present methods, there are constantly being reported disappointments of one sort or another, and various mechanical explanations have been given, vicious circles talked of, and numerous twists and kinks given to the gut in order to circumvent the difficulties. In point of fact, is the after-treatment always sufficiently cautiously proceeded with? My experience with the operation may be exceptional, but I have not encountered as yet one of these results, perhaps because the patients have usually continued for about two months after operation a course of dieting and treatment precisely as though they were recovering from acute ulcer with harmatemesis.

## ON THE FEEDING OF INFANTS WITH UNDILUTED CITRATED MILK. (a)

By FREDERICK LANGMEAD, M.D., M.R.C.P.,

Physician to Out-Patients at the Paddington Green Children's Hospital, and the Seamen's Hospital, Greenwich; Casualty Physician to St. Mary's Hospital.

It is generally agreed that few infants in the earlier months of life can digest unmodified cow's milk. The reason is not far to seek. If we take unchanged cow's milk, acidifying it with hydro-chloric acid, and then digest it with rennet, in other words, if we imitate in vitro the process of digestion in the infant's stomach, we find that the milk forms a dense tough curd. The clot of human milk, on the other hand, is soft and flocculent. The difference in the two clots is an obvious explanation of the greater indigestibility of cow's milk. This inference is confirmed by clinical experience, for with digestive disturbances tough curds are vomited and evacuated. The infant's stomach is not like the calf's, for it is unsuited to this large firm curd. Dr. Eric Pritchard (1) has pointed out, that the volume of the cow's stomach represents about 60 per cent. of the alimentary canal, whilst the volume of the human stomach is only 20 per cent. of that of the digestive tract. If we are to utilise cow's milk for infant feeding it is plain that we must discover the cause of the greater density of the curd, and prevent it. Until recently all our attention has been fixed on the chief chemical difference in the food constituents of cow's and human milk-viz., the excess of proteid in the former and the relatively greater proportion of casein. We argued in this way: "The curd is due to casein: casein is in excess in cow's milk; clearly the procedure to follow is to dilute cow's milk and so decrease the proportion of that proteid." By dilution the fat and sugar are reduced to inadequate amounts, and more has to be added artificially to correct this fault. A complicated method of feeding has thus arisen by which a different dilution is used for each month, and consequently varying additions of sugar and fat are required.

The other important factor in the phenomenon of coagulation was almost lost sight of—viz., the calcium salts. These are in considerable excess in cow's milk. Bunge gives the proportion of lime salts in human milk at .03 per cent., and in cow's Pages showed that clotting could be entirely prevented if the calcium salts were precipitated by the addition of oxalates or fluorides. No practical value was attached to this experiment until Sir Almroth Wright published a short paper in the Lancet in 1893, in which he showed that a similar result could be obtained if sodium citrate were added to the milk instead of the poisonous salts used by the two physiologists. As the outcome of a series of experiments, he found that a soft flocculent curd like that of human milk could be obtained by the addition of 2 grains of citrate of soda to an ounce of milk. He therefore suggested that infants might be fed on cow's milk, to each ounce of which 2 grains of this salt had been added. After a latent period of about eleven years Dr. Poynton was the first to partially test this method on a sufficiently large scale. In 1904, in a paper in the Lancet, he recorded the success which he had obtained with citrated milk, but he had deviated from the original suggestion of Sir Almroth Wright in that he had combined citration with dilution and had used only I grain of the citrate

to the ounce of milk.

About two years ago, at a meeting of the St. Mary's Hospital Medical Society, Sir Almroth Wright again advocated citrated undiluted milk. It was my privilege to be present at that meeting, which determined me to try this method of feeding for my out-patients at the Paddington Green Children's Hospital.

There is much to be gained by using undiluted milk. First, the food is given in a more concentrated form, and thus the liability to distension of the stomach is lessened; there is little doubt that much of the vomiting of infancy is due to physical rather than to physiological over-burdening of the stomach. Secondly, there is no need to add cream or sugar. This is of great moment to the poorclass mother who cannot afford to buy cream; which, moreover, in London, is difficult to procure free from preservative. We all know the importance of adding cream to diluted milk, yet how soon we learn also that to order it is mere waste of words! Thirdly, we avoid the calculations necessary when using diluted milk. The different dilutions at different ages, and the consequent varying amount of cream to be added, is too great a task for most mothers. Fourthly, less manipulation is required. This is always an advantage, and when dealing with slum children is one which can scarcely be overestimated.

But even remembering these great advantages, I do not think I should have ventured to depart so widely from the orthodox method, in which difficulties are met by ever-increasing dilutions, did I not know that others had successfully employed whole milk. Professor Budin, of Paris (2), has for many years fed infants on undiluted milk; sterilised by heating at 100° C. for 45 minutes, thus rendering the curd much softer, and his results have been remarkably favourable. Many other Continental physicians have followed his example. I knew also of some few pioneers in London who had fed their own babies on undiluted citrated milk, and whose temerity had been rewarded by seeing them grow strong and well.

For more than two years I have employed citration without dilution, and am more than gratified by the results. The exact method of procedure I employ is as follows:-When the baby is first brought to the hospital, supposing it is not thriving on artificial feeding, it is weighed and its weight is recorded on a chart which has been devised for the purpose; the number of feeds per diem and the amount of each feed are then determined upon. No hard-and-fast line can be drawn either with regard to the frequency or size of each meal, since so much depends upon the size and vigour of each particular child and on its previous feeding; but the following rule affords a useful standard:-For the first five weeks of life, as far as possible, meals are prescribed every 2 hours, for the second five weeks every 21 hours, and afterwards until the sixth month every 3 hours. This, of course, applies to day feeding only. By nighti.e, from 10 p.m. to 7 a.m., 2 meals are given during the first 3 weeks, one during the second three weeks, and afterwards the meals are slightly re-arranged so that the baby goes without the bottle from 11 p.m. to 5 a.m.

By Day.—1 to 5 weeks, 2 hourly feeds; 5 to 10 weeks,  $2\frac{1}{2}$  hourly feeds; 10 weeks to 6 months, 3 hourly meals,

By Night (10 p.m. to 7 a.m.).—1 to 3 weeks, 2 meals; 3 to 6 weeks, 1 meal.

For quantities I use the following table, recommended by Holt (3), slightly modified:—

FEEDI	APPROXIMATELY.			
	ozs.		ozs.	
1st week	i — iss	===	i	
2nd-3rd week	iss — iii	=	ii	
4th 5th ,,	iiss — iiiss	==	iii	
6,, 12,, ,,	iii — ivss	==	iv	
3rd 5, month	iv — vss	==	v	
5,, 9,, ,,	vss — vii	=	vi	
9,, 12,, ,,	viiss — ix	=	viii	

This table errs somewhat on the side of liberality when dealing with undiluted milk, and so I always start somewhat below the figure here given, for gastro-intestinal disturbances are the result, not of too little, but of too much food. Of necessity, there are many cases of infants far below the normal weight, and with powers of digestion, for whom a meal far smaller than the average is essential.

I then prescribe for each ounce of milk ordered 2 grains of sodium citrate, and this is given in the form of a watery solution, 1 drachm of which has to be put into each feed. For example, if 4 ounces of milk are given every 3 hours, the prescription is thus:—

Sodii citratis, oz. viii. Aquam ad., dr. i.

3 bis in die.

The mother is instructed to bring the milk to the boil, and then to add one teaspoonful to each feed. Sodium citrate is very soluble in water, so that it is possible, no matter how many ounces of milk are being given at a feed, to dissolve the citrate in I drachm of water.

By raising the milk to the boiling-point we destroy the living pathogenic micro-organisms, The report of the Medical Officer of Health for the City of London shows that this is not an unnecessary refinement. Between July and September, 1908, 23 per cent. of the samples of milk examined proved to be tuberculous, and even now, after the active pure-milk crusade, 7.7 per cent. contain living tubercle bacilli out of 285 samples. By this means, too, we render the clot still more flocculent.

At subsequent attendances the child is weighed again, at first weekly, afterwards fortnightly or every three weeks, and its weight is duly recorded. The amount of milk given is adjusted to the progress of the child, which is estimated by its general condition and the evidence of the scales. At about five months of age citration is gradually diminished, until the advent of teeth permits of unaltered milk and a more extensive dietary. If weak citrate solution is kept in a warm place a fungus is apt to grow on the surface, but this is avoided by adding a few drops of chloroform water. Equally good results are obtained if the citrate of soda is added to the milk in bulk instead of in each feed.

This method is so simple that the mother cannot easily make a mistake in preparing the milk, which is a great advantage. It requires little manipulation. It produces in the stomach a fine flocculent curd which infants can deal with, who have been screaming frequently, drawing their legs up and showing other evidences of indigestion after diluted milk. There is no danger of rickets, for it is only the excess of calcium salts, which is thrown down, which even then is still given in the milk. Moreover, Dingwall Fordyce (4) has fed rats on citrated milk, and no rickets has resulted. There is no danger of scurvy.

RESULTS.

I have now watched several of these patients from early infancy until dentition, some of whom weighed far below the average when they were first seen, and am able to say that they became strong, well-developed infants, and that rickets does not

Constipation is said to be the most troublesome effect, but I have been unable to satisfy myself that it is more in evidence in babies fed on citrated than on other forms of modified milk. The stools are more bulky, but in those patients in whom constipation has been serious it was so before they came under treatment.

Some seventy cases have been treated in this way. They were all children who were wasting under other methods of feeding. In any case in which the mother's statement that the child was getting thinner seemed to want confirming, two weighings were first taken, the first on the child's first attendance, the second after a week's interval. Many were marasmic, two or three weighing about 5 lbs. at ten weeks to two months of age. The previous feeding had been by the breast, by diluted cow's milk, and by many kinds of artificial foods. One was fed entirely on albumen-water as a last resort; three, according to their mothers' statements, were brought because they had been given up by their doctors; and in one instance a medical certificate of death had already been promised. Some have been lost eight of, as always happens in hospital practice, but, with the exception of two or three who attended for about one week only, all have gained steadily in weight, many making up for lost time and reaching normal, and above, before citration was replaced by unaltered milk.

In a lecture which I gave before the Medical Graduates' College and Polyclinic, in March, 1908, I said that I regarded this method of infant feeding as the most satisfactory which we possessed, and now, after another year's experience of its use, I am of the same opinion. I have met with no cases in the last two years in which I have found it advantageous to replace it by other kinds. must, however, be clearly understood that it is a method of feeding simply, and not a therapeutic measure such as would be required in cases of epidemic or summer diarrhœa, in which, of course,

no milk of any sort should be given.

#### CHRONIC ŒDEMAS DUE TO LOCAL DEGENERATIVE CHANGES.

BY F. PARKES WEBER, M.D., F.R.C.P., Senior Physician to the German Hospital, London, and Physician to the Mount Vernon Hospital for Chest Diseases, Hampstead.

Every medical man has probably occasionally come across cases of acquired chronic cedema of the feet, ankles and legs (often more marked in one lower extremity than the other) which occur in elderly persons, sometimes suffering from chronic rheumatoid arthritis or chronic gout, and which do not seem to be caused by any disease of the circulatory, respiratory, or urinary organs, or to belong to the class of toxamic cedemas, or to be connected with abnormal chloride-retention in the tissues. In such cases the cedema remains stationary for a long while, causes very little inconvenience, and will not yield to cardio-vascular tonics, diuretics, or any kind of drugs, though it can be temporarily removed by rest in bed and massage. There is

generally some personal and familial "arthritic" history forthcoming, and cedema of this type has often been described as an arthritic, chronic gouty, or chronic rheumatic manifestation, probably due to some alteration in the minute blood-vessels and to the effects of gravity on the lower extremities. Obesity, weak cardiac action, and low bloodpressure doubtless sometimes play a part in its production, but the patients are not always corpulent, and the blood-pressure is, I think, by no means always low. In a man, aet. 75, now under my care there is a history of his having had an attack of chronic cedema of the legs (not due to nephritis) very many years ago, which disappeared after some time under treatment by limitation of diet and a saline alkaline laxative. He has always been an active man, inclined to "good living" and corpulence. The attack of "dropsy" of the legs many years ago, whatever its cause may have been, probably predisposed the legs to the present form of chronic odema. I do not think that chlorideretention plays any part in the present trouble; special attention paid to this point in the diet has made no difference in the cedema.

The fundamental cause of the cedema in some, at least, of these cases appears to me most likely to be some degenerative change in the corium and subcutaneous tissue, perhaps specially involving the yellow elastic fibres and unstriped muscle fibres, and resulting in a loss of tissue-elasticity, that is to say, in a diminution of what may be termed the "elastic tonus" of the affected tissues. I would compare this change to the loss of elasticity in the lungs, which, occurring in the same types of individuals, gives rise to ordinary pulmonary emphysema (and probably sometimes predisposes to chronic catarrhal or cedema-like conditions of the bases of the lungs).

Another chronic condition which I believe is due to a similar diminution of "elastic tonus," and which not rarely occurs in the same types of individuals is the peculiar bulging or "puffiness" of the skin (subcutaneous tissue), giving rise to the "cushions" below the eyes, which are fairly commonly met with in elderly and degenerative individuals with arthritic personal and family history. In some such cases it appears as if the degenerative loss of tissue-elasticity not only induces an œdemalike puffiness, but likewise favours the growth of subcutaneous fat, and in such cases the puffy "cushions" below the eyes may be compared to the condition in the upper eyelids known as "ptosis adiposa" or "blepharochalasis," which may occasionally occur as a congenital abnormality, though it is more often met with as an acquired senile or degenerative condition. It is probable that these "infra-orbital cushions" and "ptosis adiposa," when congenital or appearing in early life, bear the same relation to the similar acquired conditions that cases of congenital or early developmental "trophœdema" (a) of one or both lower extremities bear to the degenerative chronic ædemas of the legs now under consideration.

In regard to the treatment of these "degenera-tive" chronic cedemas of the lower extremities, it follows that both local and general methods may be The local treatment consists in outside useful. support (bandaging, etc.) and massage, whilst the general treatment should be directed to improving the general health and delaying degenerative pro-

<sup>(</sup>a) In regard to the role of tissue-elasticity in the causation of trophodems, see F. P. Weber, remarks on trophodems in the discussion at the Royal Society of Medicine, Clinical Section, December 11th, 1908 (Proceedings, vol. ii, pp. 52, 53, and 61 to 63). In regard to the occasional combination of fatty with chronic odematous swellings it is worthy of mention that chronic trophodems of the lower extremitles has in two or three instances been accompanied by a pendulous lipomatous-like swelling of the subcutaneous tissue at the lower posterior part of the thigh.

cesses as far as possible by appropriate dietetic and other means. Amongst such means, the careful employment of thyroid extract might prove of service in a few cases, in which partial degenerative changes in the thyroid gland play a part in the pathogeny of degenerative and trophic changes elsewhere in the body. I do not think that a trial of calcium treatment is indicated in most of these cases.

## IONISATION IN THE TREATMENT OF SKIN DISEASE. (a)

By E. GRAHAM LITTLE, M.D.Lond., F.R.C.P.

AFTER some preliminary remarks on the theoretical basis of therapeutics by ionisation, Dr. Graham Little said he had had most experience with the zinc ions, which he had used with considerable success in cases of lupus vulgaris, lupus erythematosus, rodent ulcer, epithelioma, pigmented flat senile warts. The method of administration in all the cases had been similar. A galvanic battery consisting of twenty cells had been used. The positive pole had been connected with an electrode made of chemically pure zinc, the size of the electrode being graduated to the size of the patch to be treated. Where the electrode did not fit the area requiring attention, a hole had been cut in oil silk sufficiently large to expose the diseased part while protecting the healthy skin from the current. The electrode was covered with four or five thicknesses of absorbent gauze, sterilised by boiling in distilled water, and soaked in a 2 per cent, solution of zinc sulphate in distilled water. The electrode should be pressed firmly upon the skin and the current gradually introduced, cell by cell, until about 6-10 ma. were obtained, if the patient could stand the larger limit. Most patients could tolerate about 7 ma, with comparative fortitude. For lesions in which the skin was much indurated, or in which the surface was uneven, a preliminary application for some days of Beiersdorf's salicylic plaster, 25 per cent., had been useful in macerating and settening the skin. The patch to be treated should be carefully cleansed with absolute alcohol or hydrogen peroxide, and then with boiled water. The duration of the current depended on the nature of the disease and the stoicism of the patient; from 10-25 minutes would be an average time. Probably the sittings had creed on the side of shortness. The chief means of mitigating the pain was to introduce and withdraw the current gradually; the pain was really not as severe as might be thought; quite young children had stood twenty minutes with 6 ma. without serious flinching. In a case of lupus vulgaris in a delicate woman, a preliminary subcutaneous injection of cocaine had been useful in checking pain. In rodent ulcer, especially of the ulcerative stage, the treatment had succeeded admirably in at least four cases in which X-rays had comparatively failed. In lupus vulgaris the results were also very promising, but a greater number of sittings had been necessary. The effect of the treatment, as shown in two cases exhibited to the meeting, was to thin the indurated lupus patch, and to produce finally a good scar. In lupus crythematosus the best results of all had been obtained; the sittings averaged about fifteen minutes, and the scar left by the disease was particularly good. An important point was that there was little danger of doing harm or of promoting the spread of the invasion, a risk which was not negligible in many forms of treatment for this affection. A case of extensive lupus erythematosus of the semi-acutevariety was shown, in which the disease had been checked and cured by this treatment. In a case of epithelioma, shown at the meeting, which had originated in a pigmented naevus, the hardening of the epitheliomatous infiltration had been distinctly lessened by three treatments of fifteen minutes with zinc ions, and this case had failed to react to X-rays—moreover its position near the eye made the use of X-rays undesirable.

#### OPERATING THEATRES.

GREAT NORTHERN HOSPITAL. AMPUTATION OF PENIS FOR CARCINOMA.—MR. ARTHUR EDMUNDS operated on a man, æt. 55, who was suffering from a small carcinoma on the under-surface of the glans penis involving the frænum and the prepuce. The growth was of the hard, ulcerating, and nonfungating type. Glands could be felt in both groins, especially on the left side. The question that first presented itself, Mr. Edmunds pointed out, was whether a complete or a partial removal should be undertaken. This was a point difficult to settle. In the first place, amputation of the penis at the level of the scrotum is a very unsatisfactory operation. As sexual organ it is obviously useless, and micturition is liable to be accompanied by exceriation of the surrounding tissues. If the growth is so limited that amputation can be performed just behind the corona glandis, the functional result may be good; but in the present case it was impossible to perform such an operation with any reasonable hope of permanent cure, and it was decided to perform a complete amputation of the organ, trans-planting the urethra into the perinæum. This opera-tion, Mr. Edmunds said, had the disadvantage that, although the corpora cavernosa are entirely removed, the corpus spongiosum must be left for a certain distance.

The patient was placed in the lithotomy position, and a sound passed into the bladder so as to identify the urethra. An incision was then made in the middle line of the perinæum, about 2 in. long, exposing the bulb, and, with a little dissection, the crura of the corpora cavernosa. The spongy urethra was then identified and isolated from the surrounding structures; the sound was then withdrawn, and the vrethra cut across, leaving a portion sufficiently long to reach the skin without tension. The corpora cavernosa were then detached from the sides of the pubic arch, and in this way the whole of the root of the penis liberated. Hæmorrhage gave but little trouble; certain branches of the pudic artery were of necessity divided, but there was no difficulty in securing these. A second incision was now made round the root of the penis, the suspensory ligament was divided, and then, by traction on the penis, and division of a few bands of connective tissue, the whole organ was removed through the second incision. Hamorrhage was then carefully arrested. The urethra was next split on either side, so as to form two flaps, and these were fixed by sutures to the sides of the perinæal opening, the object of this being to prevent stricturing of the new meatus. rest of the perinæal wound was sutured. The anterior wound, which it could be seen was separated from this by the whole depth of the scrotum, was sutured, except for a portion where a drainage tube was inserted. At a second operation the glands on each side were re-moved. As so frequently happens, the glands were found more extensive than at first sight appeared, and it was necessary on the right side to follow them up through the crural canal into the pelvis along the external iliac artery and along the deep surface of the obturator internus. On the left side, where the glands were apparently more enlarged, there seemed to be no pelvic involvement, but one of the glands was unfortunately broken in attempting to detach it from the fascia. This involved the risk of diffusion of the growth, and to obviate this the whole wound was sponged out with undiluted carbolic acid; this necessitated drainage, as such drastic treatment leads to the effusion of a good deal of serum, but the wound, none

the less, healed quite readily.

Mr. Edmunds remarked that the

Mr. Edmunds remarked that the operation he had done on the penis involves a smaller incision than when the whole scrotum is divided, without in any way diminishing the thoroughness of the operation. It is little, if anything, more difficult, as there is plenty of room for detaching the corpora cavernosa through the posterior incision.

The subsequent result was quite satisfactory; the progress of the case was uneventful.
